CHAPTER I

INTRODUCTION

Water distribution companies face various operational challenges, particularly in managing delivery vehicles, monitoring fuel consumption, and tracking transportation expenses. Inefficient fleet management can lead to increased operational costs, inaccurate record-keeping, and difficulties in making informed business decisions. As organizations continue to seek ways to improve efficiency and reduce costs, the use of digital technologies has become essential in streamlining fleet operations and resource management.

The proposed study, Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency, aims to develop a centralized system that assists water distribution businesses in managing their fleet operations effectively. The platform is designed to monitor vehicle usage by tracking odometer readings, recording fuel consumption, and documenting transportation-related expenses. Drivers will be responsible for entering relevant trip and fuel data into the system, ensuring accurate and up-to-date records.

A key feature of the platform is its analytics and reporting capability, which provides comprehensive insights into operational performance and expenditures. By generating reports on fuel usage, vehicle mileage, and overall fleet expenses, the system enables managers to identify cost patterns, monitor efficiency, and make data-driven decisions. These analytical tools help

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

businesses optimize resource allocation, reduce unnecessary expenses, and improve operational planning.

Through the integration of fleet monitoring and business analytics, the proposed platform seeks to enhance operational transparency, improve accountability, and support cost-efficient management practices within water distribution enterprises.

1.1 Background of the Study

Water is considered one of the most essential resources in human society because it supports survival, economic stability, sanitation, environmental sustainability, and industrial development. Every community depends on water to maintain daily living activities such as drinking, cooking, cleaning, and sanitation. Beyond household use, water also plays a major role in agriculture, manufacturing, transportation support services, healthcare facilities, educational institutions, restaurants, commercial establishments, and other sectors that contribute to economic productivity. Because of its importance, the demand for reliable water services continues to increase as populations expand and urban areas develop. According to the United Nations Water (2023), sustainable water management has become one of the major global concerns due to the growing pressure placed on water systems by urbanization, industrialization, and population growth.

In many countries around the world, water distribution systems are continuously evolving to accommodate the increasing needs of communities and industries. Water providers are now expected not only to maintain a stable supply of water but also to ensure operational efficiency,

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

reliability, and sustainability in service delivery. Modern cities rely heavily on organized water distribution systems to support residential communities, public institutions, commercial centers, and industrial operations. As urban populations continue to increase, water utilities and delivery-based water providers experience greater operational pressure in maintaining efficient services while controlling costs and resource consumption.

Water distribution refers to the organized process of delivering water from supply sources to consumers through infrastructure systems such as pipelines, storage tanks, pumping facilities, delivery vehicles, and operational coordination processes. Effective water distribution does not only depend on physical infrastructure. Operational management, scheduling efficiency, resource allocation, and delivery coordination are equally important in ensuring that water reaches consumers consistently and on time. Even when infrastructure systems are available, poor operational coordination may still lead to delays, inefficient deliveries, inconsistent records, and increased operational costs.

Many organizations involved in water distribution continue to face operational challenges caused by inefficient coordination and traditional management practices. In some cases, water providers still depend heavily on manual processes such as handwritten records, paper-based scheduling, spreadsheet monitoring, and phone-call coordination between dispatchers and drivers. Although these traditional approaches may still function for smaller operations, they often become difficult to manage as customer demand increases and operational activities become more complex. As

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

organizations expand, the limitations of manual systems become more noticeable, especially in terms of scheduling, monitoring, reporting, and operational visibility.

Globally, many utility organizations and logistics-based companies are now transitioning toward digital management systems to improve efficiency and operational control. Studies explain that centralized monitoring systems help organizations improve data management, reduce operational delays, and support better decision-making processes. Modern enterprise systems are increasingly being adopted because they provide improved coordination, operational transparency, and easier access to important data needed for organizational management. In rapidly growing urban communities, organizations that continue relying solely on manual operational procedures may struggle to maintain efficiency due to increasing workloads and logistical complexity.

The increasing demand for water services is strongly connected to the continuous growth of urban populations around the world. According to the United Nations Department of Economic and Social Affairs (2022), urban populations are expected to continue increasing over the coming decades, placing additional strain on utility systems and urban infrastructure. As cities become more populated, utility providers are expected to deliver faster, more reliable, and more organized services despite increasing operational pressure. Water distribution operations must therefore adapt to changing urban conditions by improving operational coordination, scheduling systems, and resource management.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Urbanization has also contributed to increasing logistical challenges for organizations that depend on delivery operations. Traffic congestion, road construction, increasing vehicle density, and changing transportation patterns affect the ability of organizations to maintain timely deliveries. In highly urbanized areas, delivery operations may experience delays caused by congestion and inefficient coordination between drivers and administrators. These delays not only affect customer satisfaction but also contribute to fuel waste, longer travel times, higher maintenance expenses, and reduced operational productivity.

Water distribution operations are particularly sensitive to logistical inefficiencies because delays directly affect households, businesses, and institutions that rely on stable water services.

Restaurants, schools, hospitals, offices, and manufacturing facilities depend on timely water supply for their daily activities. When deliveries are delayed or operational coordination becomes ineffective, organizations may experience interruptions in services that negatively affect productivity and customer satisfaction. Because of this, water providers are increasingly expected to improve both operational management and fleet coordination.

In developing countries such as the Philippines, urbanization continues to place additional pressure on utility services and operational management systems. Cities are rapidly expanding due to economic development, migration, population growth, and increasing commercial activities. As urban communities continue to grow, the demand for stable and efficient water services also increases. Many local organizations involved in water distribution are now

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

challenged to improve operational efficiency while simultaneously managing rising fuel costs, transportation difficulties, and increasing service expectations.

The Philippines continues to experience significant urban development, particularly in commercialized and economically active cities. Expanding residential communities, growing business districts, and increasing industrial activities contribute to higher water consumption and more complex delivery operations. Utility providers and water delivery businesses must therefore adapt to changing urban conditions while maintaining efficient services. Existing operational practices that rely heavily on manual coordination may no longer be sufficient for organizations managing larger service areas and increasing customer demands.

Iloilo City is one of the urban areas in the Philippines experiencing continuous commercial and residential growth. The city has seen the expansion of residential subdivisions, educational institutions, shopping centers, restaurants, offices, and industrial facilities over recent years. This growth has increased the demand for water services in both residential and commercial sectors. As businesses and communities continue to expand, water providers are expected to deliver services more efficiently and consistently.

The continuous urbanization of Iloilo City has also contributed to increasing transportation and logistical challenges. Heavy traffic congestion, road repairs, commercial activity, and increasing vehicle volume affect delivery operations throughout the city. Delivery vehicles may encounter delays that increase fuel consumption and operational expenses. In some cases, inefficient route coordination may lead to duplicate trips, delayed deliveries, or scheduling conflicts between

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

drivers and dispatchers. These issues create operational inefficiencies that negatively affect organizational productivity.

In many water distribution operations, scheduling remains one of the most difficult aspects of operational management. Delivery schedules often change depending on customer demand, delivery availability, traffic conditions, and operational adjustments throughout the day. Organizations relying on manual scheduling methods may struggle to update schedules efficiently, especially when delivery requests increase unexpectedly. Dispatchers may experience difficulties coordinating delivery assignments, tracking completed trips, and organizing changes in schedules using paper-based or spreadsheet-based methods.

Manual scheduling systems may also increase the possibility of human error. Delivery records may become inconsistent due to inaccurate encoding, delayed updates, or missing information. In some cases, multiple deliveries may accidentally be assigned to the same vehicle or driver due to poor coordination. Administrators may also have difficulty consolidating operational records because information is stored in different formats or locations. As operations continue to expand, these inefficiencies become more difficult to manage effectively.

Another operational challenge experienced by many organizations is the lack of centralized operational monitoring. Organizations that rely primarily on manual communication between drivers and administrators may have limited visibility over ongoing operations. Managers may struggle to determine whether deliveries are completed on time, whether fuel expenses remain within operational expectations, or whether delivery schedules are being followed properly.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Without centralized monitoring systems, organizations may rely heavily on delayed reports and verbal updates from drivers.

Fleet management is another important operational component in water distribution systems. Delivery vehicles serve as essential operational resources because they transport water supplies to customers and service areas. Effective fleet management involves organizing delivery schedules, monitoring trip activities, maintaining operational records, managing fuel consumption, and ensuring efficient utilization of vehicles. However, organizations that still rely on manual recording and traditional monitoring practices may encounter difficulties maintaining organized fleet operations.

Fuel consumption is one of the major operational expenses affecting delivery-based organizations. Rising fuel prices continue to increase operational costs for businesses involved in transportation and logistics services. Poor scheduling, inefficient delivery coordination, unnecessary trips, and traffic-related delays may contribute to excessive fuel consumption. Without proper monitoring and reporting systems, organizations may struggle to identify operational inefficiencies that increase fuel expenses.

Operational costs are not limited to fuel consumption alone. Delivery delays, inefficient scheduling, extended travel times, and poor coordination may also increase vehicle maintenance expenses and labor-related costs. Vehicles operating under inefficient conditions may experience faster wear and tear due to excessive travel time and prolonged exposure to congested roads.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Organizations may therefore experience financial strain caused by operational inefficiencies that could otherwise be minimized through better coordination and monitoring.

In traditional systems, monitoring operational costs may become difficult because important records are often stored manually or encoded separately. Fuel expenses, delivery records, maintenance logs, and trip histories may not be consolidated into a centralized system. This makes it difficult for administrators to analyze operational performance accurately. Managers may also experience delays when generating reports or reviewing operational data because records must be gathered manually from multiple sources.

Operational analytics have become increasingly important in modern business environments because organizations now rely heavily on data-driven decision-making. Businesses involved in logistics and transportation operations benefit from systems capable of analyzing operational performance, monitoring expenses, and identifying inefficiencies. Analytics-based systems help organizations understand patterns in operational activities and support informed managerial decisions.

Modern enterprise management systems provide organizations with tools that improve operational coordination and centralized monitoring. These systems commonly include scheduling management, operational reporting, data consolidation, user management, and analytics functionalities that help organizations monitor ongoing activities more effectively. Organizations adopting digital systems often experience improved visibility over operations and more organized workflows compared to traditional manual processes.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Technology-based systems also improve communication between operational personnel and administrators. In manual systems, communication often depends on phone calls, handwritten updates, and delayed reporting. Digital systems help reduce communication gaps by centralizing operational information within a single platform. This allows administrators to review records, monitor operations, and analyze data more efficiently.

In logistics-based industries, centralized systems are widely recognized for improving coordination and operational transparency. Researchers explain that organizations using centralized management systems are more capable of organizing operational records, tracking performance indicators, and responding to operational concerns more efficiently. Centralized systems also help reduce data redundancy and improve the accessibility of important operational information.

Despite the availability of modern technologies, some small and medium-sized organizations continue relying on traditional operational methods due to budget limitations, lack of technological infrastructure, or resistance to operational changes. However, as organizations grow and service demands increase, manual operational methods become increasingly difficult to maintain efficiently. Organizations may eventually encounter operational bottlenecks that affect productivity, coordination, and customer satisfaction.

One major limitation of manual operational systems is the lack of structured data management. Delivery records, trip reports, fuel expenses, and scheduling information may be stored separately in notebooks, spreadsheets, or printed forms. This fragmented approach to data

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

management makes it difficult for organizations to retrieve information quickly and analyze operational performance accurately.

Another limitation involves delayed reporting and operational visibility. Administrators may not immediately receive updates regarding completed deliveries, fuel usage, or operational concerns. Delays in information sharing can affect decision-making processes because administrators rely on outdated or incomplete data. Organizations may therefore experience difficulties responding quickly to operational issues and changing delivery conditions.

The lack of centralized monitoring may also affect accountability within operations. Without organized operational records and structured reporting systems, administrators may struggle to verify delivery activities and monitor operational performance consistently. This may create challenges in evaluating productivity, identifying inefficiencies, and maintaining organized workflows.

As organizations continue adapting to changing business environments, the importance of digital transformation becomes more evident. Technology-based systems are increasingly viewed as practical solutions for improving operational management and organizational efficiency. Businesses involved in logistics, transportation, and utility services are adopting systems that support automation, centralized monitoring, analytics, and operational coordination.

In water distribution operations, technology-driven systems provide opportunities to improve scheduling coordination, operational reporting, and fleet management processes. Organizations can benefit from systems capable of organizing operational records, monitoring trip activities,

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

consolidating delivery reports, and tracking operational expenses. These functionalities help organizations improve visibility over daily operations while supporting better resource management.

Modern systems also help organizations improve operational consistency. Instead of relying solely on verbal coordination and handwritten records, organizations can maintain structured digital records accessible to authorized personnel. Centralized systems improve operational organization because information is stored systematically and can be retrieved more efficiently when needed.

The proposed study titled “Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency” aims to address the operational and logistical challenges experienced by water distribution providers through the development of a centralized management platform. The study focuses on improving operational coordination, monitoring delivery activities, organizing trip records, and supporting operational analytics for water distribution operations.

The proposed platform is designed to support administrators and drivers through a centralized operational system. Drivers will encode operational information such as trip details, fuel usage, delivery records, and other related operational data into the system. Administrators, on the other hand, will monitor encoded information, review operational reports, analyze fuel expenses, and evaluate operational performance through centralized dashboards and monitoring features.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Unlike systems heavily dependent on GPS-based monitoring technologies, the proposed platform focuses on operational reporting, encoded trip records, and centralized monitoring based on driver-submitted operational data. The system is intended to improve operational organization by consolidating information into a single platform accessible to authorized users.

The proposed system also aims to improve operational transparency by maintaining organized records of delivery schedules, fuel expenses, operational activities, and trip histories. Through centralized data management, administrators may analyze operational trends and identify areas requiring operational improvement. This supports more informed decision-making processes and improved organizational coordination.

Another important component of the proposed system involves operational analytics and reporting. The system aims to generate organized reports regarding operational performance, delivery activities, and fuel-related expenses. These reports may help administrators evaluate operational efficiency and monitor organizational costs more effectively.

Fuel monitoring is particularly important because fuel expenses represent a major portion of transportation-related operational costs. Through organized operational records and encoded trip data, administrators may monitor fuel usage trends and evaluate whether operational practices contribute to unnecessary expenses. This supports cost-control efforts and encourages more efficient operational management.

The proposed platform is also expected to improve communication and coordination between administrators and drivers. Instead of depending entirely on manual communication and

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

scattered records, operational information may be consolidated into a centralized environment where authorized personnel can review and manage operational activities more efficiently.

As Iloilo City continues to experience urban growth and increasing service demands, organizations involved in water distribution may require more organized systems capable of supporting expanding operational requirements. Traditional methods that rely heavily on manual coordination may no longer provide sufficient operational efficiency for organizations managing increasing workloads and logistical complexity.

The development of a centralized water distribution and fleet management platform therefore represents an effort to improve operational organization, reduce inefficiencies, strengthen data management, and support better operational monitoring. By integrating operational records, delivery monitoring, fuel tracking, and analytics functionalities into a centralized platform, the proposed study seeks to provide a practical and scalable solution for modern water distribution operations.

Overall, the study recognizes the growing operational challenges experienced by water distribution providers in rapidly urbanizing areas such as Iloilo City. Increasing service demands, logistical difficulties, rising operational expenses, and limitations of manual operational systems contribute to the need for more organized and technology-based management solutions. Through the development of the proposed platform, the study aims to support operational efficiency, improve cost monitoring, strengthen organizational coordination, and enhance the overall management of water distribution and fleet operations.

1.2 Statement of the Problem

Water distribution companies play a vital role in ensuring that households, businesses, and institutions receive an adequate supply of water. However, many water delivery operations continue to rely on traditional and manual methods for managing schedules, recording trips, monitoring fuel consumption, and preparing operational reports. As the scale of operations increases, these manual processes often become difficult to manage, resulting in inefficiencies, inaccuracies, and delays in decision-making.

One of the primary concerns in water distribution operations is the management of delivery schedules and fleet activities. In many organizations, delivery schedules are recorded manually through logbooks, spreadsheets, or paper-based documents. This problem exists because many small and medium-sized water distribution businesses have not yet adopted integrated digital systems due to financial constraints, lack of technological resources, or resistance to operational changes. As a result, administrators spend significant time coordinating deliveries, assigning drivers, and monitoring completed trips. The lack of automation can lead to scheduling conflicts, missed deliveries, and inefficient route planning, ultimately affecting customer satisfaction and

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

operational productivity. Investigating current scheduling and fleet management practices is necessary to identify inefficiencies and determine how technology can improve operational coordination.

Another significant challenge involves the recording and monitoring of trip information and fuel consumption. Drivers often document travel details manually, including delivery destinations, mileage, fuel usage, and completed transactions. This problem exists because there is no centralized platform that allows drivers to encode information directly into a shared database. Manual recording increases the possibility of incomplete entries, inaccurate information, lost records, and delayed submission of reports. These issues make it difficult for administrators to accurately monitor fleet performance and operational expenses. Since fuel costs represent a major portion of transportation expenses, inaccurate fuel monitoring can result in poor budgeting, undetected wastage, and ineffective cost-control measures. Therefore, it is important to investigate how current documentation practices affect the reliability of operational data and financial monitoring.

The absence of structured trip documentation also creates challenges in maintaining historical operational records. Without a standardized system for recording and storing delivery information, organizations may experience difficulties retrieving past records when needed for audits, performance evaluations, or business planning. This problem exists because data is often dispersed across multiple files, notebooks, or individual reports rather than stored in a centralized repository. The resulting fragmentation of information reduces data accessibility and increases

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

the time required to locate important records. Consequently, management may struggle to analyze operational trends, identify recurring issues, and implement data-driven improvements. Investigating the impact of unstructured documentation is necessary to understand how centralized data management can enhance organizational efficiency.

Another issue arises from delays in consolidating operational data and generating reports. In many cases, administrators must manually collect information from multiple drivers, verify records, and compile reports before obtaining a complete view of operational performance. This problem exists because current systems lack automated reporting mechanisms that can process and summarize operational data in real time. The manual consolidation process consumes valuable administrative resources and increases the likelihood of human error. Delayed reporting can hinder management's ability to respond promptly to operational issues, monitor performance indicators, and make informed business decisions. Investigating reporting inefficiencies can help identify opportunities for automation and improved decision support.

Communication between drivers and administrators also presents operational challenges. In the absence of a centralized platform, communication often depends on phone calls, text messages, or face-to-face interactions. This fragmented communication approach can lead to misunderstandings, delayed updates, and incomplete information exchange. Such communication gaps can affect delivery coordination, fleet monitoring, and problem resolution during daily operations. Understanding the impact of communication inefficiencies is important

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

because effective information sharing is essential for maintaining smooth and reliable water distribution services.

Furthermore, the lack of a centralized management system limits the organization's ability to monitor overall fleet performance. Administrators may find it difficult to track vehicle utilization, fuel efficiency, delivery completion rates, and operational productivity when information is scattered across various records. This problem exists because traditional methods do not provide integrated analytics and performance monitoring tools. As a result, management may have limited visibility into operational strengths and weaknesses, reducing their ability to implement strategic improvements. Investigating fleet performance monitoring practices is necessary to determine how data analytics can support better operational planning and resource management.

Given these challenges, there is a need to develop an Enterprise Water Distribution and Fleet Management Platform that integrates driver-based trip data encoding, centralized data management, automated reporting, and operational analytics. Such a system has the potential to improve efficiency, enhance data accuracy, strengthen communication, support fuel cost monitoring, and provide administrators with reliable information for decision-making.

Specifically, this study seeks to answer the following questions:

1. How are current water distribution and fleet operations managed in terms of delivery scheduling, trip recording, fuel usage documentation, and delivery reporting?

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

2. What problems are encountered in the current system in terms of manual data recording, difficulty in tracking fuel consumption, lack of structured trip documentation, delays in consolidating operational data, and inefficiencies in monitoring delivery performance?
 3. How does the absence of a centralized system affect the accuracy of operational records, communication between drivers and administrators, monitoring of fleet performance, and decision-making in water distribution operations?
 4. What system features can be developed to address these issues, specifically a driver-based input system for trip data encoding, centralized data management for administrators, and automated reporting and analytics for operational performance?
 5. How can the proposed system improve operational efficiency, enhance data accuracy, support cost monitoring, particularly fuel usage, and strengthen decision-making in water distribution and fleet management operations?
-

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

1.3 OBJECTIVE OF THE STUDY

1.3.1 GENERAL OBJECTIVE

The general objective of this study is to design and develop a centralized fleet management and water distribution system that utilizes system monitoring and automated routing to optimize logistical efficiency, enhance service reliability, and reduce operational costs.

The increasing demand for efficient water distribution services has created a need for organizations to adopt modern technological solutions that can support operational management and resource optimization. Water distribution businesses rely heavily on effective coordination among personnel, vehicles, inventory resources, and delivery schedules to ensure that customer demands are met promptly and accurately. However, many organizations continue to depend on manual processes for recording transactions, scheduling deliveries, monitoring fleet activities, and tracking operational expenses. These traditional methods often result in fragmented information, delayed communication, inaccurate records, and inefficiencies that negatively affect overall business performance. Consequently, there is a growing need for integrated systems that can centralize operational activities and provide management with better control over daily operations.

The proposed study seeks to address these challenges through the development of a centralized fleet management and water distribution system capable of integrating multiple operational processes into a single platform. The system is intended to serve as a comprehensive management tool that allows administrators to organize customer orders, schedule deliveries, manage drivers, monitor vehicle utilization, track fuel consumption, and generate operational reports. By consolidating these activities into

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

one system, the proposed platform aims to eliminate the inefficiencies associated with maintaining separate records and manual documentation procedures. Centralized management not only improves data accessibility but also ensures that information remains accurate, consistent, and readily available to authorized users.

A major component of the proposed system is the implementation of system monitoring capabilities. Monitoring plays a critical role in modern fleet and logistics management because it provides visibility into operational activities and resource utilization. Through system monitoring, administrators can observe delivery progress, review driver activities, evaluate vehicle performance, and monitor fuel consumption records. Access to real-time operational information enables management to respond quickly to emerging issues and make informed decisions based on current conditions. This capability is particularly important in water distribution operations, where delays, vehicle breakdowns, inventory shortages, and communication gaps can significantly affect service quality and customer satisfaction. By providing administrators with timely and accurate information, the system contributes to improved operational oversight and more effective management practices.

Another significant objective of the proposed system is the utilization of automated routing mechanisms to improve delivery efficiency. In many water distribution businesses, route planning is performed manually, often relying on personal experience and familiarity with delivery areas. While this approach may be adequate for small-scale operations, it becomes increasingly difficult to manage as the number of customers, delivery requests, and service locations grows. Inefficient route planning can lead to longer travel times, excessive fuel consumption, increased vehicle wear and tear, and reduced productivity. To address these concerns, the proposed system aims to automate aspects of the routing process by organizing delivery destinations in a manner that supports efficient transportation and resource utilization.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

By reducing unnecessary travel distances and improving delivery coordination, the system can contribute to faster service completion and lower operational expenses.

The study also seeks to enhance service reliability by improving the accuracy and consistency of operational processes. Service reliability is a critical factor in customer satisfaction because customers expect deliveries to arrive on schedule and according to agreed service requirements. Delays, missed deliveries, and inaccurate scheduling can negatively affect customer trust and business reputation.

Through the implementation of structured scheduling procedures, centralized order management, and delivery monitoring functionalities, the proposed system aims to strengthen the organization's ability to provide dependable and consistent service. The availability of organized records and automated processes further reduces the likelihood of human errors that commonly occur in manual systems.

In addition to improving operational efficiency, the proposed study aims to support cost reduction initiatives within water distribution operations. Transportation-related expenses, particularly fuel consumption and vehicle maintenance costs, represent a substantial portion of operational expenditures in distribution businesses. Without appropriate monitoring mechanisms, organizations may find it difficult to identify inefficiencies that contribute to unnecessary expenses. The proposed system addresses this issue by providing tools for recording fuel consumption, monitoring vehicle usage, and analyzing operational performance. These capabilities enable management to evaluate cost-related trends and identify opportunities for improvement. By promoting more efficient resource utilization, the system can help organizations reduce operational costs while maintaining service quality.

Furthermore, the proposed platform seeks to improve organizational decision-making through the generation of reports and analytical information. Effective management requires access to reliable data that can be used to evaluate performance, monitor progress, and support strategic planning. In many

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

traditional environments, generating reports often involves manually consolidating information from multiple records, which can be time-consuming and prone to errors. The proposed system automates the collection and processing of operational data, allowing reports to be generated more efficiently and accurately. These reports may include information related to delivery performance, fuel expenditures, vehicle utilization, inventory status, and workforce productivity. The availability of such information supports evidence-based decision-making and enables management to identify operational strengths, weaknesses, and areas requiring improvement.

Another important aspect of the study is its contribution to digital transformation within water distribution operations. As organizations increasingly adopt technology-driven solutions to remain competitive and responsive to market demands, the integration of information systems has become a strategic necessity. The proposed fleet management and water distribution platform aligns with this trend by introducing automation, centralized data management, and intelligent monitoring capabilities into an operational environment that may otherwise rely on manual procedures. Through the adoption of these technologies, organizations can improve efficiency, strengthen internal controls, and enhance their capacity to manage growing operational demands.

Ultimately, the general objective of this study is not only to develop a functional software solution but also to create a comprehensive management platform that addresses the operational challenges faced by water distribution businesses. By integrating fleet management, delivery coordination, system monitoring, fuel tracking, and automated routing within a centralized environment, the proposed system seeks to improve logistical efficiency, strengthen service reliability, optimize resource utilization, and support cost-effective business operations. Through these improvements, the study aims to contribute to the

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

modernization of water distribution management practices and provide organizations with a sustainable technological solution capable of supporting long-term operational growth and efficiency.

1.3.2 Specific Objectives

To achieve this goal, the study aims to:

Assess the current water distribution and fleet management operations in terms of delivery scheduling, trip recording, fuel usage documentation, and delivery reporting.

This objective aims to understand how the organization currently manages its daily operations. Before developing a solution, it is necessary to examine the existing workflow and identify how tasks are performed. Delivery scheduling determines how water deliveries are planned and assigned to drivers. Efficient scheduling is important because it helps ensure that customer demands are met on time while minimizing delays and operational inefficiencies.

Trip recording is another critical aspect because it documents vehicle movements, delivery locations, distances traveled, and completed deliveries. Accurate trip records provide valuable operational information that can be used for monitoring fleet activities and evaluating driver performance.

Fuel usage documentation is equally important because fuel expenses represent a significant operational cost in transportation-based businesses. Monitoring fuel consumption allows

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

management to identify excessive fuel usage, detect inefficiencies, and improve cost control strategies.

Delivery reporting serves as the foundation for evaluating operational performance. Reports provide management with information regarding completed deliveries, delivery volumes, operational issues, and overall productivity. Assessing these operational components allows the researchers to understand the current situation and establish the basis for system improvement.

Identify the operational problems encountered in the existing system, particularly in manual data recording, fuel consumption tracking, trip documentation, operational reporting, and delivery monitoring.

This objective focuses on determining the weaknesses and limitations of the current operational process. Many organizations continue to rely on manual methods such as handwritten records, paper forms, and spreadsheets. While these methods may be sufficient for small-scale operations, they often become inefficient as operational activities increase.

Manual data recording can result in errors, missing information, duplicate entries, and difficulties in retrieving records. Fuel consumption tracking becomes challenging when records are not updated consistently or verified accurately. Poor trip documentation may lead to incomplete historical records, making it difficult to review previous operations when needed.

Operational reporting often requires significant time and effort because administrators must manually gather information from multiple sources. This delays decision-making and increases

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

the possibility of inaccurate reports. Similarly, inadequate delivery monitoring can reduce management's visibility into ongoing operations, making it difficult to identify delays, operational bottlenecks, or service issues. Identifying these problems is essential because effective solutions can only be developed when the root causes of inefficiencies are clearly understood.

Determine how the absence of a centralized management system affects operational efficiency, communication between drivers and administrators, accuracy of records, and decision-making processes.

This objective examines the impact of not having a unified platform for managing operational data. In many organizations, information is stored in different locations, such as paper records, spreadsheets, and individual reports. This fragmentation of information can create difficulties in accessing, updating, and verifying operational data.

Operational efficiency is negatively affected because employees spend additional time searching for information, consolidating records, and coordinating activities. Communication between drivers and administrators may become inconsistent when updates are transmitted through phone calls, text messages, or verbal communication. Such methods can lead to misunderstandings, delayed responses, and incomplete information sharing.

Record accuracy may also suffer because multiple versions of the same information may exist, increasing the risk of inconsistencies and errors. Furthermore, management decisions become more difficult when accurate and up-to-date information is unavailable. By investigating these

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

effects, the study can demonstrate the importance of centralized information management in supporting efficient operations.

Develop a centralized system that allows drivers to encode trip-related operational data while enabling administrators to monitor deliveries, fuel usage, and operational performance through centralized data management and analytics.

This objective represents the development component of the study. Based on the findings from the assessment and problem identification stages, the researchers aim to create a centralized platform capable of addressing operational challenges.

The driver-based data encoding feature allows drivers to directly input operational information such as trip details, delivery records, fuel consumption, and completed transactions into the system. This reduces dependence on paper-based documentation and improves data accuracy.

Centralized data management ensures that all operational information is stored in a single database, making records easier to access, organize, and retrieve. This eliminates data fragmentation and improves information consistency across the organization.

Monitoring and analytics features enable administrators to view operational performance through dashboards, reports, and summarized data. These tools provide real-time visibility into fleet activities, delivery performance, and fuel usage trends. The inclusion of analytics helps transform raw operational data into meaningful information that supports better management decisions.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Evaluate how the proposed system can improve operational efficiency, enhance data accuracy, strengthen operational monitoring, support fuel cost analysis, and improve decision-making in water distribution and fleet management operations.

This objective focuses on measuring the effectiveness of the proposed system after development. Evaluation is important because it determines whether the system successfully addresses the identified operational challenges.

Operational efficiency is expected to improve through the automation of routine tasks, reduction of paperwork, and faster access to information. Data accuracy should increase because information is encoded directly into the system, reducing manual transcription errors and data duplication.

Operational monitoring becomes more effective because administrators can access real-time information regarding deliveries, fleet activities, and driver performance. Fuel cost analysis is strengthened through systematic recording and reporting of fuel consumption data, allowing management to identify trends, monitor expenses, and implement cost-saving measures.

Improved decision-making is another expected benefit because managers will have access to accurate, timely, and comprehensive operational information. Through data-driven insights and performance analytics, management can make informed decisions regarding resource allocation, operational planning, fleet utilization, and overall business strategy. Evaluating these improvements helps determine the overall value and effectiveness of the proposed Enterprise Water Distribution and Fleet Management Platform.

1.4 Scope and Delimitation

Scope and Delimitation of the Study

The primary focus of this study is the development of an Enterprise Water Distribution and Fleet Management Platform designed to improve the efficiency, organization, and monitoring of water distribution operations. The proposed system is a web-based platform that provides a centralized environment for managing delivery activities, fleet operations, fuel consumption records, and operational reporting. The system is intended for internal organizational use and is accessible only to authorized users, particularly administrators, drivers, and business owners involved in the daily operations of water distribution services.

The increasing demand for efficient water distribution requires organizations to maintain accurate records of deliveries, vehicle utilization, fuel expenses, and operational performance. Many small and medium-sized water distribution businesses still rely on manual methods of recording trip information, fuel consumption, delivery schedules, and vehicle usage. These traditional processes often result in data inconsistencies, delayed reporting, difficulties in monitoring operational activities, and challenges in evaluating business performance. To address these concerns, the proposed system aims to digitize and centralize operational records through a unified platform that can support more effective management and decision-making.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

The system will provide comprehensive fleet management capabilities. Administrators will be able to register and maintain vehicle records, including vehicle identification details, capacity information, maintenance schedules, and operational status. Through the system, administrators can monitor vehicle availability and utilization to ensure that delivery resources are properly allocated. The centralized storage of vehicle information will eliminate the need for scattered paper-based records and improve accessibility to operational data whenever needed.

Another major component of the system is delivery management. The platform will allow administrators to create and manage delivery schedules based on customer requirements and operational priorities. Delivery assignments can be organized and recorded within the system to ensure that all scheduled deliveries are properly documented. By maintaining a digital record of delivery activities, the organization can improve accountability, reduce scheduling conflicts, and ensure that delivery operations are executed efficiently.

The proposed system also includes trip monitoring through encoded records and delivery logs. Drivers will be responsible for entering operational data related to their assigned deliveries. These records may include trip dates, delivery destinations, vehicle used, fuel consumption, quantity of water delivered, and other relevant delivery information. The driver's role within the system is limited primarily to data entry and updating delivery-related records. Administrative functions, monitoring activities, report generation, and data management responsibilities remain under the control of authorized administrators. This separation of responsibilities helps maintain data integrity and ensures that operational information is managed centrally.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Fuel monitoring is another important feature covered by the system. Fuel expenses represent a significant operational cost in water distribution businesses. The proposed platform allows fuel consumption records to be documented and stored systematically. Administrators can review fuel usage reports and compare fuel consumption across different vehicles and delivery operations. The availability of organized fuel records can help management identify unusual fuel usage patterns, evaluate operational efficiency, and support cost-control initiatives.

In addition to operational recording, the system will provide reporting and analytics functionalities. Administrators and business owners will be able to generate reports related to fleet performance, delivery activities, fuel consumption, and operational costs. These reports will serve as valuable tools for evaluating business operations and identifying areas that require improvement. Historical records stored within the system can also be analyzed to support future planning, budgeting, and resource allocation decisions. By transforming operational data into meaningful reports, the system contributes to better organizational decision-making.

The platform is also designed to improve information accessibility and record management. Since all operational data are stored within a centralized database, authorized users can access necessary information without searching through multiple files or paper documents. This centralized approach minimizes data redundancy, improves data consistency, and enhances the overall efficiency of record management processes. Furthermore, the system promotes transparency by providing a clear audit trail of operational activities and recorded transactions.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Another significant aspect of the study is route optimization based on historical operational records and trip data. Rather than relying solely on experience-based decision-making, administrators can review previous delivery records to identify efficient delivery patterns and operational trends. Information gathered from completed trips may assist management in evaluating delivery performance, planning future schedules, and reducing unnecessary operational expenses. This approach contributes to the overall objective of improving cost efficiency within the organization.

Despite its capabilities, the proposed system has several limitations. The system does not utilize Global Positioning System (GPS) technology for real-time vehicle tracking. Vehicle monitoring is performed through manually encoded trip records, delivery logs, and administrative updates entered into the platform. As a result, the system cannot display the live location of delivery vehicles or provide real-time route navigation features. Instead, operational monitoring depends on the accuracy and completeness of the information entered by authorized users.

Furthermore, the study is limited to internal operational management and does not include customer-facing functionalities. Features such as online ordering, customer self-service portals, online payment processing, and public delivery tracking are not included in the scope of the proposed system. The platform is specifically designed to support internal business operations rather than customer interaction and e-commerce activities.

The proposed system also excludes advanced technologies such as artificial intelligence-based route planning, predictive maintenance systems, Internet of Things (IoT) sensors, automated fuel

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

monitoring devices, and third-party logistics integrations. While these technologies may enhance operational efficiency, their implementation is beyond the objectives, resources, and timeframe of the current study. Future researchers may consider integrating these advanced features to further improve the functionality of the system.

Additionally, the system is designed specifically for water distribution operations and may not be directly applicable to other industries without significant modifications. The database structure, reporting features, and operational workflows are tailored to the requirements of water delivery businesses. Therefore, the results and implementation of the study are limited to the operational environment for which the system is developed.

Overall, the study focuses on the design, development, and implementation of a web-based platform that supports fleet management, delivery monitoring, fuel tracking, operational reporting, and cost-efficiency analysis for water distribution businesses. By centralizing operational data and providing structured management tools, the proposed system seeks to improve organizational efficiency, enhance record accuracy, support informed decision-making, and contribute to more effective management of water distribution and fleet operations.

The proposed Enterprise Water Distribution and Fleet Management Platform is subject to the following limitations and boundaries:

- The system is designed exclusively for internal use by authorized personnel, including administrators, drivers, and business owners involved in water distribution operations.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

- The system focuses only on water distribution and fleet management processes and does not support operations outside the organization's distribution activities.
- The system does not utilize GPS technology for real-time vehicle tracking. Monitoring is based solely on encoded trip records, delivery logs, and administrative updates entered into the system.
- The system does not provide real-time route navigation or live vehicle location monitoring.
- Drivers are limited to encoding and submitting operational data such as trip information, delivery records, and fuel consumption details. Administrative functions remain accessible only to authorized administrators.
- The system does not include online customer ordering, customer self-service portals, or public delivery tracking features.
- Online payment processing and financial transaction management are not included in the proposed system.
- The system does not support mobile application functionality and is designed primarily as a web-based platform.
- Integration with third-party logistics providers, external business systems, or enterprise resource planning (ERP) platforms is not included.
- The system does not incorporate artificial intelligence, machine learning, or predictive analytics for automated decision-making.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

- Automated route optimization using GPS data and traffic information is beyond the scope of the study. Route evaluation is based only on historical trip records and operational data stored within the system.
- The system does not include automated fuel monitoring devices or Internet of Things (IoT)-based vehicle sensors. Fuel consumption records are manually entered by authorized users.
- Vehicle maintenance scheduling and monitoring are limited to recording and managing maintenance information and do not include automated maintenance prediction features.
- The study is limited to the design, development, implementation, and evaluation of the proposed system within the selected operational environment and timeframe of the research.
- The effectiveness of the system depends on the accuracy, completeness, and timeliness of the data entered by authorized users.

1.5 Significance of the Study

The development and implementation of the Enterprise Water Distribution and Fleet Management Platform offer substantial advantages across multiple operational and community sectors. By shifting from fragmented, manual record-keeping to a centralized digital framework, this study provides distinct, measurable benefits to the following stakeholders:

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

- **Water Distribution Owners**

The platform serves as a critical strategic tool for water distribution enterprise owners by replacing opaque, paper-based operations with comprehensive data transparency.

Through the automated consolidation of driver-encoded trip histories, maintenance logs, and financial records, owners are equipped with real-time analytics and centralized dashboards. This high-level oversight eliminates corporate blind spots, allowing owners to closely monitor operational overheads, isolate sources of financial leakage, and track structural fuel expenses. Ultimately, the system empowers owners with accurate, fact-based business intelligence, transforming how they control long-term operational costs and execute critical managerial decisions.

- **Authorized Personnel (Administrators)**

For the administrators tasked with handling day-to-day logistics, the system drastically diminishes the administrative friction inherent in traditional, manual management setups. By centralizing driver schedules, vehicle assignments, and delivery tracking into a unified web-based administrative module, the platform eliminates the chaos of uncoordinated communication channels like phone calls and disjointed spreadsheets. This automated structure reduces human error during data encoding, accelerates the consolidation of end-of-day operational performance metrics, and ensures data integrity across the corporate ledger. Administrators gain a reliable, structured method for

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

enforcing accountability, balancing driver workloads, and managing fleet assets efficiently.

- **Fleet drivers**

benefit directly from the optimization of daily workflows and improved workplace ergonomics. Shifting away from paper schedules and uncoordinated routes minimizes the stress, confusion, and cognitive fatigue associated with logistically inefficient distribution corridors. By receiving organized schedules and system-optimized routes, drivers can navigate high-traffic urban corridors with minimal operational delays. This reduction in unnecessary travel times and duplicate trips drastically lowers total fuel consumption and mitigates physical vehicle wear and tear. Consequently, drivers experience a safer, more predictable, and highly structured working environment.

- **Iloilo City Community**

The community of Iloilo City stands as the ultimate beneficiary of the system through the indirect but profound improvement in downstream public service utility reliability. Rapid urbanization, ongoing road construction, and mounting traffic density across expanding commercial and residential sectors often result in severe water delivery delays under traditional manual delivery regimes. Because local households, academic institutions,

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Medical facilities, restaurants, and commercial hubs rely heavily on consistent water access for basic sanitation, economic productivity, and daily operations, logistical bottlenecks create immediate community vulnerabilities.

By equipping local water providers with automated routing algorithms and centralized delivery monitoring, the platform directly mitigates these urban distribution bottlenecks. It safeguards the community against sudden service interruptions, improves delivery punctuality, and establishes a highly consistent supply chain. Through maximized resource allocation and optimized vehicle utilization, the system ensures that Iloilo City's rapidly growing zones maintain access to an essential resource, thereby supporting public¹ health, enhancing consumer satisfaction, and bolstering local economic stability.

1.6 Definition of Terms

Analytics Dashboard

- *Conceptual Definition:* A data management tool that visually tracks, analyzes, and displays key performance indicators (KPI), metrics, and key data points to monitor the health of a business or specific process.
- *Operational Definition:* The primary interface within the web platform where administrators and owners view consolidated reports on fuel usage, vehicle mileage, and fleet expenses generated from driver-encoded data.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Centralized Data Management

- *Conceptual Definition:* The process of consolidating data from multiple sources into a single, unified repository to ensure consistency, security, and ease of access.
- *Operational Definition:* The use of a centralized Firebase database to store all water delivery schedules, trip logs, and fuel records, replacing traditional manual methods such as notebooks and spreadsheets.

Cost Efficiency

- *Conceptual Definition:* The act of saving money by making a product or performing an activity in a better way, often by reducing waste or optimizing resources.
- *Operational Definition:* The reduction of operational overheads in water distribution—specifically fuel and maintenance costs—achieved through the identification of cost patterns in the system’s analytical reports.

Data Integrity

- *Conceptual Definition:* The maintenance and assurance of the accuracy and consistency of data over its entire lifecycle.
- *Operational Definition:* The systematic validation of delivery information through separated user roles, where drivers provide raw data entry and administrators perform monitoring and verification within the platform.

Digital Transformation

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

- *Conceptual Definition:* The integration of digital technology into all areas of a business, fundamentally changing how organizations operate and deliver value to customers.
- *Operational Definition:* The transition of the water distribution enterprise from traditional paper-based coordination and phone-call scheduling to the proposed web-based enterprise management system.

Enterprise Management System

- *Conceptual Definition:* Large-scale software packages that track and control all of the complex operations of a business, including resource allocation and reporting.
- *Operational Definition:* The web-based platform designed specifically for internal organizational use to digitize and manage fleet operations and logistical workflows.

Fuel Monitoring

- *Conceptual Definition:* The process of observing and recording the consumption of fuel to manage costs and detect inefficiencies or theft.
- *Operational Definition:* A system feature that allows drivers to encode fuel usage data and administrators to review and compare reports across different vehicles to support cost-control initiatives.

Logistical Inefficiency

- *Conceptual Definition:* Failures within a supply chain or distribution network that lead to delays, wasted resources, and increased costs.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

- *Operational Definition:* Problems identified in current water operations, such as duplicate trips, delayed deliveries, and inaccurate fuel records caused by manual scheduling methods.

Operational Transparency

- *Conceptual Definition:* The degree to which an organization's activities and performance are visible to internal stakeholders.
- *Operational Definition:* The availability of a clear digital audit trail within the platform, allowing business owners to see completed deliveries and verified trip histories at any time.

Route Optimization

- *Conceptual Definition:* The process of determining the most cost-effective route for a vehicle based on various factors like distance and traffic.
- *Operational Definition:* The identification of efficient delivery patterns through the analysis of historical trip data and encoded logs stored within the system database.

Vehicle Utilization

- *Conceptual Definition:* A metric used to measure how effectively a fleet's vehicles are being used compared to their total capacity or availability.
- *Operational Definition:* The record of vehicle availability and mileage tracked in the platform to ensure delivery resources are properly allocated for water distribution.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

CHAPTER 2

REVIEW OF RELATED LITERATURE AND STUDIES

2.1 Foreign Studies

Fuel Consumption Monitoring

According to a study published in The Aeronautical Journal (1983), aircraft operators experienced several challenges related to unreliable fuel-associated systems and inaccurate fuel gauging mechanisms. The study explained that traditional analogue systems often increased pilot workload and reduced operational efficiency, particularly during system malfunctions. To address these issues, researchers developed digital and microprocessor-based fuel management systems capable of integrating fuel measurement, transfer, and warning functions into a centralized management platform.

The researchers found that digital fuel management systems improved operational reliability, enhanced fuel monitoring accuracy, reduced workload, and supported automated fault detection and system reconfiguration. Furthermore, the study emphasized the importance of centralized utility management systems in improving operational control and decision-making processes.

This literature is relevant to the current study because it highlights how centralized and automated monitoring systems can improve operational efficiency and data accuracy. Similar to the proposed enterprise water distribution and fleet management platform, the implementation of digital monitoring and centralized data management may help improve fuel usage tracking, operational reporting, and overall fleet performance.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Integrated Water Management

Mitchell (2006) explored the application of Integrated Urban Water Management (IUWM) concepts in Australia through the analysis of 15 urban development case studies. The study explained that IUWM supports the integration of water supply, stormwater, and wastewater management systems to improve operational efficiency and reduce environmental impacts. The findings revealed that integrated management approaches contributed to the development of efficient urban water systems and improved overall water cycle management.

The study further emphasized the importance of monitoring system performance, enhancing organizational coordination, and improving knowledge dissemination among public and private sectors involved in water management operations. Additionally, the researchers highlighted that centralized and integrated management systems support better operational monitoring and decision-making processes.

This literature is relevant to the current study because it highlights the importance of centralized management and operational monitoring in water distribution systems. Similar to the proposed enterprise water distribution and fleet management platform, integrated management systems may improve operational efficiency, reporting accuracy, and coordination in water distribution and fleet operations.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Production and Distribution Integration

Chen and Vairaktarakis (2005) studied a make-to-order production and distribution system involving suppliers and customers with scheduled order deliveries and operational cost considerations. The researchers emphasized the importance of integrating production scheduling and distribution planning to improve delivery performance and reduce operational costs. The study developed scheduling and delivery approaches that optimized delivery tardiness and minimized total distribution expenses.

The findings revealed that integrated production and distribution systems performed more efficiently compared to sequential operational approaches. The researchers further explained that integrated scheduling systems improve delivery coordination, enhance operational decision-making, and support faster and more reliable logistics operations. In addition, the study highlighted the effectiveness of automated and optimized scheduling approaches in improving operational performance.

This literature is relevant to the present study because it supports the importance of integrated management systems in logistics and distribution operations. Similar to the proposed enterprise water distribution and fleet management platform, the integration of delivery scheduling, operational monitoring, and centralized management may improve efficiency, reduce operational delays, and support better decision-making processes.

Enterprise Project Management Systems

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

According to Zhang (2021), traditional digital business platforms for enterprise project management systems are no longer sufficient to meet the growing operational demands of modern organizations. The study proposed the integration of information technology into enterprise-level project management systems to improve system functionality, operational efficiency, and management performance. The researcher emphasized that modern digital platforms support better coordination, centralized management, and improved business operations.

The findings revealed that integrating information technology into enterprise project management systems enhances organizational performance and strengthens operational monitoring and management processes. Furthermore, the study highlighted the importance of adopting advanced digital systems to improve efficiency and support more effective enterprise operations.

This literature is relevant to the current study because it supports the significance of centralized digital platforms and integrated management systems in improving operational efficiency.

Similar to the proposed enterprise water distribution and fleet management platform, the use of information technology may improve monitoring processes, operational management, and decision-making capabilities.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Transportation Management Systems

Griffis and Goldsby (2007) examined the adoption and non-adoption experiences of Transportation Management System (TMS) technology across various companies. The study revealed that TMS adopters come from diverse industries and often utilize outsourced services to support decision-making and transportation-related operations. The researchers found that organizations adopt TMS based on strategic operational needs, although the system's functionality is primarily focused on daily transportation and logistics activities.

The study further indicated that while expectations regarding system performance and return on investment vary among organizations, users generally report high satisfaction with TMS implementation. In contrast, non-adopters consider transportation decision-support systems a lower priority within their operations. The researchers also discussed the future development and expansion of TMS technology in improving logistics efficiency and operational decision-making.

This literature is relevant to the current study because it highlights the importance of centralized transportation management systems in improving operational efficiency and decision-making processes. Similar to the proposed enterprise water distribution and fleet management platform, the integration of transportation management systems can enhance delivery scheduling, fleet coordination, and overall logistics performance.

Delivery Route Management Systems

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

A study on delivery route management based on the Dijkstra algorithm examined the efficiency of delivery operations in terms of punctuality, cost reduction, and route optimization. The researchers highlighted that many small and medium enterprises still rely on traditional methods for managing delivery routes, which often result in inefficient scheduling, increased costs, and higher chances of operational errors.

The study proposed the use of the Dijkstra algorithm to improve delivery route selection and scheduling. A delivery management system was developed to assist managers and drivers in determining the most efficient routes for order distribution. The findings revealed that the algorithm performed effectively in optimizing delivery routes, reducing travel time, and improving overall delivery efficiency.

This literature is relevant to the current study because it emphasizes the importance of automated and optimized route planning in improving fleet and delivery operations. Similar to the proposed enterprise water distribution and fleet management platform, the integration of routing algorithms and digital management systems can enhance delivery efficiency, reduce fuel consumption, and improve operational performance.

Digital Monitoring and Imaging Systems

Lu, Yan, and Colechin (2004) developed an imaging-based multifunctional instrumentation system for online monitoring and characterization of fossil fuel-fired flames. The system utilized optical probes, spectral beam splitting, and high-performance charge-coupled device (CCD)

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

cameras to capture flame images. These images were transmitted to a microcomputer, where they were converted into digital data for further processing.

The researchers applied digital image processing techniques, including two-color pyrometry and spectral analysis, to extract key flame parameters such as ignition point, flame area, brightness, temperature, and stability indicators. The results of their experiments demonstrated that the system could provide real-time and continuous measurement of flame conditions, which are highly sensitive to combustion performance.

This literature is relevant to the present study because it highlights the effectiveness of digital monitoring systems in improving real-time data collection and operational accuracy. Similar to the proposed enterprise water distribution and fleet management platform, the use of digital monitoring and automated data processing can enhance system efficiency, improve operational decision-making, and support more accurate performance tracking.

Operation Management Systems and Workflow Optimization

Kashihara, Miyazawa, and Hayashi (2011) proposed the Operation Record Analysis System (OPERAS), a system designed to analyze and improve operating workflows as part of continuous operational enhancement. The study emphasized that organizations, particularly telecommunications operators, must reduce human errors and operational costs to ensure efficient and reliable service delivery. However, operational procedures are often based on predefined workflows that may not fully account for all real-world conditions, leading to variations in actual execution and reliance on human judgment.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

To address these issues, the researchers introduced a system that quantitatively assesses actual operating procedures and uses the results to optimize workflow design. The OPERAS framework supports the recording of operational activities, management of workflows, and generation of operational statistics for analysis and improvement. The system was tested in a simulated network installation scenario, demonstrating its capability to monitor workflows and provide data-driven insights for operational enhancement.

This literature is relevant to the current study because it highlights the importance of automated workflow recording, analysis, and optimization in improving operational efficiency. Similar to the proposed enterprise water distribution and fleet management platform, the integration of a centralized system for recording and analyzing operations can help reduce human error, improve data accuracy, and enhance decision-making processes.

Web-Based Product Data Management Systems

Liu and Xu (2001) reviewed product data management (PDM) systems and their evolution toward web-based technologies in industrial environments. The study explained that PDM integrates and manages all information related to a product, from design and manufacturing to end-user support. It serves as an integration tool that ensures the right information is available in the right format to the right users at the right time, resulting in improved efficiency, reduced errors, and minimized redundancy in organizational workflows.

The authors emphasized that the emergence of web-based technologies significantly enhanced traditional PDM systems by improving information accessibility and system integration across

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

distributed environments. However, they also highlighted challenges in implementing centralized information systems due to dynamic enterprise structures, inconsistent IT requirements, and varying departmental processes. As a result, web-based PDM systems were proposed as a more flexible and scalable solution for managing complex and evolving enterprise data environments.

This literature is relevant to the present study because it highlights the importance of centralized and integrated information systems in improving operational efficiency and data management.

Similar to the proposed enterprise water distribution and fleet management platform, the use of web-based systems can enhance information sharing, improve workflow efficiency, and support better decision-making processes

Integrated Decision Support Systems .

Liu, Duffy, Whitfield, and colleagues (2010) reviewed the development of decision support systems (DSS), focusing on the emerging concept of integrated decision support systems (IDSS). The study explained that traditional standalone DSS technologies are no longer sufficient to meet the increasing complexity of modern decision-making environments. As a result, researchers have shifted toward developing integrated systems that combine multiple tools, data sources, and technologies to improve decision support performance.

The authors analyzed over 100 studies and software systems related to IDSS and classified them based on different integration perspectives and supporting technologies. The findings highlighted that system integration significantly enhances the quality and efficiency of decision-making processes by providing better access to information and improving analytical capabilities. The

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

study also identified future challenges in system integration and emphasized the importance of continued research in this area.

This literature is relevant to the present study because it emphasizes the importance of integrated systems in improving decision-making efficiency and data management. Similar to the proposed enterprise water distribution and fleet management platform, integrated decision support systems can enhance operational monitoring, improve data accuracy, and support more effective management decisions.

Fuel Reduction Treatment Cost Analysis

Rummer (2008) conducted a critical review of the costs associated with fuel reduction treatments in forest resource management. The study explained that operational costs are commonly used to evaluate treatment effectiveness, compare alternatives, estimate project expenses, and support national resource management strategies. However, the author noted that many of the existing cost estimates used in previous studies lack a strong empirical basis, resulting in uncertainty in decision-making processes.

The review identified that different approaches have been used in estimating fuel treatment costs, but there are still significant gaps in understanding operational expenses. These gaps include business overhead costs, equipment repair and maintenance reserves, and risk-related cost estimation. The study further emphasized that cost variability is influenced by site conditions, treatment methods, and market factors, making it difficult to generalize cost assumptions across different contexts.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

This literature is relevant to the present study because it highlights the importance of accurate cost monitoring and reliable operational data in managing resources effectively. Similar to the proposed enterprise water distribution and fleet management platform, having a centralized system for tracking operational costs such as fuel usage can improve cost accuracy, enhance decision-making, and support more efficient resource management.

Project Monitoring Systems for Cost Control

Al-Jibouri (2003) examined different project monitoring systems and their effectiveness in controlling project cost and performance in construction management. The study described how monitoring systems use various performance measures to assess project progress and identify deviations from planned schedules and budgets. These systems were first evaluated theoretically and then tested using simulation models to assess their practical effectiveness.

The researcher developed a project simulation model that realistically represented project progress and incorporated factors such as changes in project plans and inflation rates. The results showed that different monitoring systems respond differently to changes in project conditions, with some systems providing more accurate and timely feedback than others. The study also found that the Activity-Based Ratios technique offered a clearer and more straightforward indication of overall project progress compared to other methods.

This literature is relevant to the present study because it highlights the importance of effective monitoring systems in tracking operational performance and controlling costs. Similar to the proposed enterprise water distribution and fleet management platform, implementing a

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

monitoring system can improve cost tracking, enhance operational visibility, and support better decision-making in fleet and delivery operations.

Logistics Management Systems in Manufacturing Operations

Sullivan and Fordyce (1990) examined IBM's Logistics Management System (LMS), a real-time integrated decision and knowledge-based expert support system used in IBM's semiconductor manufacturing facility in Burlington, Vermont. The system functions as a dispatcher and monitoring tool that manages and controls the manufacturing flow of microelectronic chips and modules used across IBM product lines.

The study explained that LMS operates as a transaction-based system that supports real-time decision-making and improves coordination within manufacturing operations. It was developed by IBM's advanced industrial engineering department to enhance production efficiency and ensure smooth workflow management. The researchers found that the system significantly improved manufacturing performance and played a critical role in managing key areas of the production facility.

This literature is relevant to the present study because it highlights the importance of real-time monitoring and integrated decision support systems in improving operational efficiency. Similar to the proposed enterprise water distribution and fleet management platform, the use of centralized logistics and monitoring systems can enhance workflow coordination, improve data accuracy, and support better operational decision-making.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Fleet Management Systems and Traffic Control Synergies

Kotsialos and Vassilakopoulou (2023) conducted a systematic literature review on the synergies between fleet management enterprise systems and traffic control systems. The study emphasized that integrating information sharing and collaborative planning between these systems can significantly improve operational efficiency, safety, and environmental sustainability.

The authors identified five main research themes: hazardous goods transportation, environmental impact and emissions reduction, positioning and navigation technologies, traffic management, and fleet operations optimization. The findings highlighted that many studies focus on social responsibility concerns, particularly reducing accidents in hazardous transport and minimizing environmental impact, which underscores the importance of sustainability in transportation systems.

However, the study also revealed that despite the strong potential for integration, there is still limited research on the coordination between real-time fleet management and traffic control measures such as route guidance, ramp metering, variable speed limits, and signal control systems. This gap suggests opportunities for further development of integrated transportation and fleet management solutions.

This literature is relevant to the present study because it supports the importance of integrated and centralized systems in improving fleet operations. Similar to the proposed enterprise water distribution and fleet management platform, the integration of fleet management and control

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

systems can enhance operational efficiency, improve decision-making, and support cost-effective logistics management.

Impact of Business Analytics on Operational Performance

Chae, Yang, Olson, and Sheu (2014) examined the impact of business analytics (BA) resources, particularly accurate manufacturing data and advanced analytics, on operational performance.

The study emphasized that both data accuracy and the use of advanced analytical tools, such as mathematical optimization techniques, are important resources for improving manufacturing planning, control processes, and overall operational efficiency.

The researchers applied a contingent resource-based theory (RBT) framework, suggesting that the effectiveness of business analytics depends on complementary organizational resources.

Using survey data from the Global Manufacturing Research Group (GMRG), the study found that fact-based supply chain management (SCM) initiatives, such as Total Quality Management (TQM), Just-In-Time (JIT), and statistical process control, play a mediating and moderating role in enhancing operational performance.

The findings revealed that the impact of advanced analytics is not standalone but depends on the presence of accurate data and supporting SCM practices. The study concluded that organizations can achieve improved operational performance when business analytics initiatives are integrated with strong data quality management and fact-based operational practices.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

This literature is relevant to the present study because it highlights the importance of accurate data and analytical systems in improving operational efficiency and decision-making. Similar to the proposed enterprise water distribution and fleet management platform, the integration of accurate data collection, analytics, and centralized management can enhance operational performance, cost efficiency, and decision support in fleet and logistics operations.

Operational Analytics in Business Performance Prediction

Bera (2021) explored the application of operational analytics in improving business processes through data-driven decision-making and process optimization. The study emphasized that operational analytics serves as a business tool for resource management and data streamlining, which enhances productivity, employee engagement, customer satisfaction, and investment planning.

The research demonstrated how insights can be extracted through various stages of data analysis, including exploratory data analysis, predictive modeling, documentation, and reporting. A real-world dataset involving restaurant sales revenue was used to develop predictive models, including linear regression, ridge regression, and decision tree regression. The study further applied a second-stage regression model to improve prediction accuracy and analyzed factors such as annual sales trends, food preferences across cities, demand variability during weekends, and model performance comparisons using ensemble methods.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

The findings highlighted the effectiveness of operational analytics in forecasting business performance and supporting strategic decision-making. The study also suggested future research directions in improving predictive accuracy and expanding analytical techniques.

This literature is relevant to the present study because it highlights the importance of data-driven systems in improving operational efficiency and decision-making. Similar to the proposed enterprise water distribution and fleet management platform, operational analytics can enhance forecasting, resource allocation, and performance monitoring in logistics and fleet operations.

Third-party logistics performance and service provision

According to Liu and Lyons (2011), the operational performance and service capabilities of third-party logistics (3PL) providers play a significant role in achieving organizational efficiency and financial performance. Their study evaluated logistics providers in the United Kingdom and Taiwan to determine the relationship between service provision and operational effectiveness. The findings revealed that operational excellence is more important than simply offering a wide range of services. The researchers emphasized that logistics providers that align their services with customer priorities are more likely to achieve better operational and financial outcomes. The study also highlighted the importance of effective operational management, service coordination, and performance evaluation in logistics operations.

This study is relevant to the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency because it supports the need for efficient operational processes and structured service management within distribution-related industries.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Similar to the findings of Liu and Lyons (2011), the proposed system aims to improve operational performance through organized delivery scheduling, fuel usage monitoring, trip recording, and centralized reporting. The study further supports the importance of integrating operational analytics and management systems to improve efficiency and decision-making in enterprise distribution operations.

Transportation management

According to van Heeswijk et al. (2019), transportation management plays a vital role in modern logistics and supply chain operations. The study discussed the fundamental elements of transportation network design, including transportation modes, loading units, transportation scheduling, and intermodal transportation systems. The researchers emphasized that effective transportation management improves coordination, operational efficiency, and resource utilization within integrated logistics networks. The study also explored advanced transportation concepts such as synchromodal transportation, long-haul transportation management, and last-mile transportation operations. Furthermore, it highlighted the importance of research trends and technologies in improving transportation systems and operational decision-making.

This study is relevant to the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency because it supports the importance of organized transportation operations and integrated management systems in distribution-related industries. The concepts presented by van Heeswijk et al. (2019) are related to the proposed system's objective of improving delivery scheduling, operational coordination, trip

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

documentation, and resource management. The study also supports the integration of operational analytics and centralized management processes to improve efficiency and overall transportation performance in water distribution operations.

robust parameter design in process optimization

According to Taguchi (2007), robust parameter design focuses on identifying process settings and product design parameters that remain stable despite variations in uncontrollable factors, also known as noise factors. The concept emphasizes the importance of achieving consistent performance by minimizing the effects of uncertainty in production and operational environments. Taguchi introduced innovative approaches in experimental design and process optimization, which significantly influenced modern quality control and engineering practices. Although some of his methods have been debated and criticized, his work laid the foundation for improving product and process robustness in industrial systems.

The study also explains that modern approaches to robust parameter design incorporate response surface methodologies and advanced statistical techniques to further enhance process optimization. These methods aim to achieve the same objective introduced by Taguchi, which is to improve system performance under varying conditions. This concept is relevant to operational systems that require consistency, efficiency, and reliability, especially in environments where process variability can affect performance outcomes.

smart logistics in operations management

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

According to Feng and Ye (2021), smart logistics has emerged as a significant development in the logistics industry due to the increasing complexity and volume of global logistics operations. The study explains that the integration of online and offline channels in logistics has created new challenges that require more advanced and intelligent solutions. Technologies such as the Internet of Things (IoT), information and communication technology (ICT), and artificial intelligence (AI) are being used to improve the efficiency and effectiveness of logistics operations.

The authors further emphasize that smart logistics is reshaping traditional logistics management by introducing more data-driven and technology-based approaches. Research in this field focuses on system frameworks, operational models, optimization problems, and the application of emerging technologies in real-world logistics scenarios. The study also highlights the importance of identifying research gaps and addressing industry needs to guide future developments in logistics operations management.

This study is relevant to the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency because it supports the importance of digital transformation and intelligent systems in managing complex distribution operations. Similar to smart logistics systems, the proposed platform aims to improve operational efficiency through centralized data management, automated reporting, and optimized delivery processes. It also reflects the need for technology-driven solutions to handle increasing operational demands and improve decision-making in enterprise distribution systems.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

computerized performance monitoring systems in organizational control

According to Irving, Higgins, and Safayeni (1986), computerized performance monitoring and control systems can produce both positive and negative effects in organizational settings. Their exploratory study compared clerical workers in organizations using computerized monitoring systems with those in organizations that did not use such systems. The findings revealed that computerized monitoring contributes to perceived improvements in office productivity, more accurate and complete assessment of employee performance, and stronger organizational control.

However, the study also identified several negative impacts associated with computerized monitoring systems. Workers reported increased stress levels, reduced job satisfaction, and weakened relationships with peers and management. The study further noted that managers tend to overemphasize quantitative performance measures while underestimating qualitative aspects of employee work. These findings highlight the complexity of implementing computerized monitoring systems in organizational environments.

This study is relevant to the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency because it demonstrates the importance of balancing operational monitoring with employee and system usability considerations. Similar to computerized monitoring systems, the proposed platform involves tracking operational activities such as deliveries, fuel usage, and trip records to improve efficiency and decision-making. The study emphasizes that while monitoring systems can enhance productivity

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

and control, careful system design is necessary to avoid negative effects such as user dissatisfaction and over-reliance on quantitative metrics.

role of analytics for operational risk management in the era of big data

According to Araz, Choi, Olson, and Salman (2020), operational risk management (ORM) is a critical function in organizations, especially in the context of the growing availability of big data and advanced analytics. Their study examines recent developments in operational risk management literature from a data analytics perspective, focusing on how analytical tools are increasingly being used to improve decision-making and risk control in operational environments.

The authors highlight that operational risks are influenced by various natural and man-made disruptions that affect organizational performance across different sectors. To address these risks, organizations are adopting data-driven approaches that integrate monitoring systems, analytical models, and decision-support tools. The study classifies ORM literature based on application areas, analytical techniques, and implementation strategies, emphasizing the importance of structured data usage in managing operational uncertainties.

Furthermore, the study explains that integrating data analytics into operational risk management enables organizations to improve monitoring, enhance predictive capabilities, and support more effective decision-making processes. The authors also emphasize the need for continuous development of analytical frameworks to support evolving operational environments and complex systems.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

This study is relevant to the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency because water distribution and fleet operations involve multiple operational risks such as delays, fuel inefficiencies, manual recording errors, and coordination issues. Similar to ORM systems, the proposed platform aims to reduce operational risks through centralized data management, automated reporting, and data-driven decision support. It also supports improved monitoring and operational control to ensure efficiency and reliability in enterprise distribution processes.

reliability and accuracy of operational system data in emergency service databases

According to Heino et al. (2019), the reliability and accuracy of data in operational systems are critical for ensuring the validity of clinical and operational decision-making. Their nationwide study evaluated the FinnHEMS helicopter emergency service (HEMS) clinical quality registry by analyzing how accurately physicians and paramedics documented operational and clinical information based on standardized fictional scenarios.

The results showed varying levels of agreement depending on the type of data recorded. High agreement was observed in areas such as dispatch coding, mission status, and operational timing, indicating that these types of information can be reliably documented in a centralized system. However, lower agreement levels were found in certain clinical parameters and secondary measurements, suggesting inconsistencies in data recording practices and potential issues in data quality and standardization.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

The study concludes that while operational data in emergency service systems can be collected reliably, there are still areas where documentation accuracy needs improvement. This highlights the importance of consistent data entry standards and system design improvements to enhance overall data quality and reliability in operational environments.

This study is relevant to the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency because it emphasizes the importance of accurate and reliable data recording in operational systems. Similar to emergency service databases, water distribution and fleet management systems depend on precise documentation of trips, fuel usage, deliveries, and operational events. Ensuring data accuracy in the proposed system is essential for improving decision-making, operational efficiency, and overall system reliability.

Study on Microprocessor-Based Monitoring

Beeny (1983) established that consolidating data measuring and transfer tasks onto a digital microprocessor platform enhances structural reliability, lowers manual workload, and supports prompt fault detection compared to traditional analog mechanisms.

This study is relevant to the current study because it validates the technical transition from manual tracking to an automated digital platform, supporting the development of the system's core automated data logging features.

Study on Integrated Management Frameworks

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Mitchell (2006) analyzed multiple urban frameworks and determined that adopting integrated management methodologies directly improves overall operational monitoring, resource cycle management, and cross-organizational coordination.

This study is relevant to the current study because it provides an operational foundation for integrating multiple distinct data modules into a single, cohesive administrative dashboard.

Study on Synchronized Operational Scheduling

Chen and Vairaktarakis (2005) investigated combined scheduling structures and revealed that synchronized operational frameworks generate vastly higher delivery punctuality and lower overall distribution costs than sequential, disjointed methods.

This study is relevant to the current study because it supports the system's primary goal of optimizing workflow timelines, proving that synchronized task scheduling lowers institutional overhead.

Study on Modern Enterprise Platforms

Wang et al. (2020) demonstrated that modern digital enterprise platforms optimize organization-wide visibility, eliminate information silos, and support highly accurate

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

administrative monitoring. This study is relevant to the current study because it mathematically and operationally justifies the deployment of centralized management software to ensure real-time data transparency across departments.

Study on Automated Activity Logging

Kashihara et al. (2011) introduced workflow optimization metrics through recording platforms, confirming that automated activity logging supplies vital data-driven insights needed to eliminate human recording errors.

This study is relevant to the current study because it justifies the inclusion of background activity logging and automated tracking within the software to maintain data integrity.

Study on Collaborative Information Architecture

Liu and Xu (2001) reviewed collaborative information architecture and web-based frameworks, establishing that centralized data management systems reduce database redundancy and drastically elevate data accessibility across changing corporate environments.

This study is relevant to the current study because it provides the architectural rationale for utilizing web-accessible database setups that allow administrators to access records securely from any location.

Study on Continuous Digital Monitoring

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Lu et al. (2004) proved that continuous digital monitoring and automated processing instrumentation successfully achieve real-time data collection and enhanced accuracy during highly sensitive performance tracking.

This study is relevant to the current study because it demonstrates that continuous data ingestion minimizes lagging metrics, ensuring the proposed system displays accurate, live operational updates.

Study on Decision Support Frameworks

Liu et al. (2010) examined multi-tool environments and noted that integrating varied data streams into a single decision support platform heavily optimizes overall analytical capabilities and information retrieval speeds.

This study is relevant to the current study because it supports the implementation of the system's analytics module, proving that unified dashboards empower administrators to make faster, fact-based choices.

2.2 Local Studies

Smart Water Management Systems for Operational Efficiency and Sustainability

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Austria and Lacbay (2025) investigated the implementation of a Smart Water Management System (SWMS) using IoT sensors, data analytics, and machine learning to improve water resource management and operational efficiency.

This study is relevant to the current study because it supports the integration of IoT-based monitoring, real-time data collection, and predictive analytics within the platform to optimize water distribution operations and reduce operational costs.

Water Resource Development and Management Challenges in the Philippines

Inocencio and Barker (2018) examined challenges in water resource development and management in the Philippines, emphasizing the need for improved planning and resource utilization.

This study is relevant to the current study because it highlights the importance of efficient water management systems, which the proposed platform seeks to achieve through centralized monitoring and operational optimization.

Water Governance and Information Management Systems

Malenab et al. (2016) assessed water governance practices and identified limitations in monitoring, evaluation, and information management systems.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

This study is relevant to the current study because it justifies the development of an integrated platform that enhances information management, coordination, and decision-making in water distribution operations.

Financial Sustainability of Water Distribution Systems

Bohm, Essenburg, and Fox (1993) evaluated the financial sustainability of rural water systems and emphasized the importance of cost recovery and operational efficiency.

This study is relevant to the current study because it supports the need for cost-efficient operational strategies and resource management features that can improve financial sustainability in water utilities.

Challenges in Water Supply Distribution and Infrastructure Maintenance

Magwilang and Paredes (2023) identified challenges related to water supply adequacy, distribution, and infrastructure maintenance in rural communities.

This study is relevant to the current study because it highlights the need for monitoring and maintenance management functions that can be incorporated into the proposed platform to improve service delivery.

GIS and Remote Sensing Technologies in Water Resource Planning

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Galinato and Santillan (2020) utilized GIS and remote sensing technologies to identify alternative water sources and support sustainable water resource planning.

This study is relevant to the current study because it supports the integration of GIS-based mapping and location monitoring features for efficient water distribution and fleet management.

Leak Detection Technologies for Water Distribution Networks

Ferino et al. (2018) developed a leak detection system using vibration sensors and FFT techniques to identify water losses in pipeline networks.

This study is relevant to the current study because it demonstrates the importance of leak detection technologies that can be integrated into the platform to minimize water losses and improve operational efficiency.

Advanced Leak Detection Using Impulse Radar Technology

Bacarro et al. (2021) investigated the use of impulse radar technology for detecting underground pipe leaks and identifying pipeline conditions.

This study is relevant to the current study because it supports the implementation of advanced monitoring technologies that can assist in preventive maintenance and reduce operational costs.

Participatory Approaches in Resource Management

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

According to the literature, there has been a growing shift from traditional top-down management approaches toward more participatory and community-centered approaches in environmental and resource management. Top-down approaches often rely heavily on professional expertise and centralized decision-making, which may overlook the experiences, needs, and knowledge of local stakeholders. In contrast, bottom-up approaches encourage the involvement of local communities in planning, decision-making, and implementation processes, recognizing that those directly affected by operations possess valuable insights that can contribute to more effective management practices. The participation of stakeholders helps improve communication, promotes transparency, and ensures that decisions are aligned with actual operational needs.

The study is important because it highlights the significance of involving users and stakeholders in management and decision-making processes rather than relying solely on centralized control. However, the literature also emphasizes that participatory approaches are not without limitations. Challenges such as token participation, lack of resources, insufficient knowledge, and difficulties in coordination may reduce the effectiveness of community involvement if not properly managed. These issues demonstrate the need for systems and tools that can facilitate communication, information sharing, and coordination among stakeholders while maintaining structured management processes.

This literature is relevant to the proposed Centralized Fleet Management and Water Distribution System because the system aims to improve coordination and information management among

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

individuals involved in water distribution operations. By providing a centralized platform for recording deliveries, monitoring fleet activities, tracking fuel consumption, and generating reports, the system supports a more collaborative and transparent operational environment. The findings of the study reinforce the importance of ensuring that operational data is accessible to authorized users and that communication between administrators and personnel is streamlined. Furthermore, the literature supports the need for technology-based solutions that can address organizational challenges while enabling informed decision-making and efficient resource management.

User Acceptance of Integrated Water Management Technologies

Ignacio et al. (2019) examined user acceptance of integrated water management technologies in water-scarce communities.

This study is relevant to the current study because it highlights the importance of user acceptance and usability considerations in the successful implementation of water management platforms.

Water Demand Management and Resource Optimization

Abansi et al. (2018) analyzed water demand management initiatives and emphasized efficiency, equity, and sustainability in water resource management.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

This study is relevant to the current study because it supports the use of data-driven management tools to optimize water distribution and improve resource allocation.

Water Quality Monitoring and Public Health Protection

Moe et al. (1991) investigated the relationship between drinking water quality and the occurrence of diarrheal diseases among children.

This study is relevant to the current study because it highlights the importance of maintaining reliable and safe water distribution systems through effective monitoring and management.

Potable Water Service Delivery and Institutional Efficiency

Israel (2009) examined local potable water service delivery and identified institutional challenges affecting water accessibility and service quality.

This study is relevant to the current study because it supports the development of centralized management systems that improve operational coordination and service efficiency.

Climate Resilience and Infrastructure Management in Water Systems

Moya (2018) evaluated the resilience of Philippine irrigation systems and emphasized the importance of infrastructure maintenance and adaptive management.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

This study is relevant to the current study because it justifies the inclusion of maintenance scheduling and monitoring features that can improve the reliability of water distribution operations.

Optimization Approaches for Sustainable Urban Water Supply

Roco et al. (2022) explored sustainable urban water supply planning through optimization models and alternative water management strategies.

This study is relevant to the current study because it supports the implementation of optimization tools that enhance operational efficiency, resource utilization, and cost management within water distribution systems.

Social Acceptance of Integrated Water Systems in Water-Scarce Communities

According to Jonathan Jared Ignacio, Roy Alvin Malenab, Carla Mae Pausta, Arnel Beltran, Lawrence Belo, Renan Ma. Tanhueco, Michael Angelo Promentilla, and Aileen Orbecido (2019), the Integrated Water System (IWS) offers alternative water and sanitation solutions that can benefit rural communities experiencing water scarcity. The system consists of three major components: the Rainwater Harvesting System (RWHS), Water Treatment System (WTS), and Eco-Toilet System (ETS). These components provide various benefits, including access to water for domestic use, improved sanitation, environmental protection, public health promotion, and food security. The researchers investigated the social acceptance of the IWS in Mulanay, Quezon

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Province, Philippines, using the Combined Technology Acceptance Model and Theory of Planned Behavior (C-TAM-TPB). Their findings revealed that users' attitudes toward the system significantly influenced their behavioral intention to use and accept the technology. The study emphasizes that positive perceptions and user acceptance are essential factors for the successful implementation and sustainability of integrated water and sanitation projects in water-scarce communities.

Optimization of Gravity-Fed Water Distribution Systems in Indigenous Rural Communities

Magwilang, Armas, Paredes, Bugnay, and Dagupen (2023) examined the optimization of a gravity-fed water distribution system in a mountain indigenous community in Bontoc, Philippines. The study addressed common challenges faced by rural water supply systems, including low water velocity, pipe clogging, tank spills, and unequal water distribution among households. Using EPANET software, the researchers resized distribution pipes to improve water flow efficiency and developed analytical models to determine the maximum number of taps per water source, variations in water service time, and the appropriate service hours for each manifold. Their findings demonstrated that optimizing the existing gravity-fed water supply system can significantly reduce pipeline clogging, prevent water wastage from tank overflows, and promote a more equitable distribution of water resources within the community. The study highlights the importance of applying engineering and analytical approaches to improve the sustainability and efficiency of water supply systems in rural and water-scarce areas.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Inter-Basin Water Transfer Systems for Climate-Resilient Water Supply Management

Ricacho, Valencia, Claro, Xu, and Rajarathnam (2026) investigated the feasibility of an inter-basin water transfer (IBWT) system as a solution to climate-induced water scarcity in the Philippines. The study proposed connecting the water-rich Agusan River Basin to the water-deficient Mananga River Basin in Cebu through a 412-kilometer pipeline capable of supplying up to 63.9 million cubic meters of water annually. Using hydraulic modeling and geospatial analyses, the researchers optimized the pipeline route to reduce environmental impacts and construction costs while supporting sustainable development goals. The findings indicated that the project could significantly improve water availability in Cebu, increasing the supply by approximately 58.26 liters per capita per day and helping address the region's persistent water shortages. Furthermore, the study highlighted the economic viability of the project, projecting substantial financial returns, employment generation, and long-term benefits for regional development. The researchers also emphasized the environmental advantages of utilizing existing hydropower infrastructure for pumping operations, which could considerably reduce carbon emissions. Overall, the study demonstrates the potential of inter-basin water transfer systems as a sustainable and climate-resilient strategy for enhancing water security in the Philippines.

Agricultural Water Resource Development and Irrigation Management in the Philippines

Inocencio and Barker (2018) examined the challenges of agricultural water resource development and management in the Philippines amid growing concerns over water scarcity and

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

flooding. The authors discussed the historical development of irrigation systems and highlighted trends in irrigation investments, including the expansion of both public and private irrigation projects. Their study revealed a significant increase in private investments, particularly in pumps and shallow tube wells, as well as greater investment in communal irrigation systems. Despite these developments, persistent issues remain in planning, design, management, operation, and maintenance of irrigation facilities. The authors emphasized the need to rethink current approaches to agricultural water resource management to enhance water productivity and sustainability. Furthermore, they argued that climate change is likely to intensify water-related challenges and may hinder the country's ability to achieve food security without continued dependence on rice imports (Inocencio & Barker, 2018).

Water-Saving Irrigation Technologies for Sustainable Rice Production

Tabbal et al. (2002) investigated water-saving irrigation techniques and alternative crop establishment methods for rice production in the Philippines in response to increasing water scarcity. Their study compared traditional transplanted rice with direct wet-seeded and direct dry-seeded rice systems. The findings revealed that direct wet-seeded rice produced yields that were 3–17% higher than traditional transplanted rice while requiring 19% less water and improving water productivity by 25–48%. Direct dry-seeded rice achieved comparable yields and demonstrated the ability to utilize early-season rainfall more effectively, thereby conserving irrigation water for subsequent cropping seasons. The researchers also found that maintaining soil moisture near saturation reduced water inputs and increased water productivity, although

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

slight yield reductions occurred. Furthermore, groundwater depth significantly influenced water use efficiency and the potential for water savings. The study concluded that the adoption of water-saving technologies can enhance rice production efficiency and contribute to sustainable agricultural water management, although such practices may also affect hydrological processes at larger spatial scales.

Non-Revenue Water Management and Water Loss Reduction Strategies

Cervancia et al. (2022) examined the issue of non-revenue water (NRW) in a water distribution utility by assessing operational practices and identifying factors contributing to water losses. Using interviews and simple linear regression analysis, the researchers investigated the relationship between real water losses and pressure variations, as well as the relationship between apparent losses and the number of service connections. The findings revealed that only the number of service connections showed a significant relationship with apparent water losses, making it the largest contributor to NRW. Based on the results, the study recommended several strategies to reduce water losses, including maintaining records of infrastructure age, improving the accuracy of water meter readings, implementing a water meter repair and replacement program, and conducting regular monitoring to prevent water theft. The authors also emphasized the importance of establishing a dedicated department focused on NRW reduction through standardized zoning, assessment, and monitoring procedures to improve water utility performance and revenue generation.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Drinking Water Governance and Integrated Resource Management in the Philippines

Smith (1999) examined drinking water issues and management in the Philippines from a political geographic perspective, emphasizing the importance of effective water governance in developing countries. The study highlights that equitable access to safe drinking water is a critical component of sustainable development. It also points out that water distribution in the Philippines is influenced by socio-political and economic factors, often resulting in inequality among communities. Smith (1999) further argues that watershed-based and integrated natural resource management approaches are essential in addressing these challenges. In addition, the study stresses that access to safe drinking water should be recognized as a human rights issue to promote environmental justice and social equity.

Israel (2009) reviewed the local service delivery of potable water in the Philippines, analyzing both national conditions and case study areas such as Dumaguete City and Agusan del Sur. The study found that although laws, institutions, strategies, and programs related to potable water service delivery were already in place, several institutional problems still persist. It further noted that the Philippines was progressing toward meeting its national and Millennium Development Goals (MDGs) for potable water provision; however, additional efforts were still necessary to achieve these targets within the limited timeframe. In the case study findings, Dumaguete City was identified as

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

having met or being close to meeting potable water delivery objectives, while Agusan del Sur and some of its municipalities still faced significant challenges. Israel (2009) also emphasized that price, quality, and accessibility of potable water were key factors influencing household choices of water sources. Moreover, the study highlighted that institutional issues remain the primary challenges affecting local water service delivery in the country.

Water Service Quality, Reliability, and Customer Satisfaction Assessment

According to Preña et al. (2026), achieving safe and reliable water services remains a major challenge in rapidly urbanizing cities in the Philippines. Through a large-scale household survey conducted in Legazpi City, the researchers evaluated water service delivery based on water quality, supply reliability, staff performance, customer support, and billing. The findings revealed that households were generally satisfied with staff courtesy and billing accuracy. However, persistent issues related to water quality, weak water pressure, frequent service interruptions, and inadequate communication from service providers were identified. The study emphasized the importance of infrastructure investments, transparency, and institutionalized customer feedback mechanisms to improve water service governance and support progress toward Sustainable Development Goal 6.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

According to Ito (2022), infrastructure development in the Philippines continues to lag behind that of other ASEAN countries despite notable achievements in Public–Private Partnerships (PPPs). The study examined the current status of infrastructure development and highlighted the role of PPPs in addressing infrastructure gaps. Through case studies of the Metro Manila Water Concession Project and the Metro Rail Transit (MRT) Line 3 Project, the author demonstrated both the strengths and challenges of the PPP model. The Metro Manila Water Concession Project was recognized as one of the most successful PPP initiatives in the water sector, providing significant benefits to residents through improved water services. However, issues such as sustainable water source development remain concerns. In contrast, the MRT Line 3 Project was identified as a less successful PPP venture due to operational defects and continued reliance on government subsidies. These findings suggest that while PPPs can contribute to infrastructure development and service delivery, they also involve complex risks and challenges that require effective governance and long-term planning.

Water Governance Reforms and Institutional Development in the Philippines

Rola et al. (2016) examined the drivers of water governance reforms in the Philippines and analyzed the conditions necessary for developing a water governance framework that can effectively respond to future water demands. Using a stage-based approach to institutional reforms, the study evaluated the outcomes of previous water governance

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

initiatives and identified persistent challenges, including conflicts between customary and formal regulations, disparities between urban and rural water management systems, upstream and downstream resource issues, and controversies surrounding water supply privatization in Metro Manila. The findings revealed that many past reforms were largely symbolic and procedural, resulting in limited structural changes to support legal and institutional frameworks. Based on these findings, the authors advocated for a decentralized water governance system implemented at the watershed level to improve coordination, sustainability, and responsiveness in water resource management. The study highlights the importance of comprehensive institutional reforms in achieving effective and equitable water governance in the Philippines.

Decentralized Water Governance and Watershed-Based Resource Management

Rola, Abansi, Arcala-Hall, Lizada, Siason, and Araral (2016) examined the factors influencing water governance reforms in the Philippines and assessed the conditions necessary for establishing a governance framework capable of meeting future water demands. Using a stage-based approach to institutional reform, the study analyzed previous water governance initiatives and identified persistent challenges, including conflicts between customary and formal regulations, disparities between urban and rural water systems, upstream and downstream resource management issues, and debates surrounding water privatization in Metro Manila. The authors found that many reforms were largely symbolic and procedural, resulting in limited structural changes to

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

strengthen legal and institutional frameworks. Consequently, they advocated for a decentralized water governance model implemented at the watershed level to improve coordination, sustainability, and responsiveness in managing water resources. The study highlights the importance of comprehensive institutional reforms and effective governance structures in addressing the country's long-term water management challenges.

Water Refilling Stations as Alternative Sources of Safe Drinking Water

Magtibay (2004) examined the growing role of water refilling stations as an alternative source of drinking water in the Philippines. The study noted that management issues in water utilities, poor environmental conditions, and outbreaks of waterborne diseases such as cholera have led many consumers to seek safer drinking water sources. As a result, the demand for purified water from water refilling stations has significantly increased. According to the study, purified water produced by these facilities generally meets the national standards for drinking water and often exhibits higher quality than water supplied through traditional distribution systems due to the removal of impurities. However, to ensure public health and water safety, the government regulates the operation of water refilling stations by enforcing sanitation standards and monitoring critical components such as water sources, purification systems, facilities, personnel, and product handling practices. The study highlights the importance of proper regulation and

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

quality assurance in maintaining safe and reliable drinking water supplies for communities.

Climate Change Impacts on Water Availability and Watershed Sustainability

Cacal, Mehboob, and Bañares (2024) investigated the potential impacts of climate change on future surface water availability in the Irawan Watershed of Puerto Princesa, Philippines, using the Water Evaluation and Planning (WEAP) model within an Integrated Water Resource Management (IWRM) framework. The study utilized bias-corrected General Circulation Models (GCMs) under four Shared Socioeconomic Pathways (SSPs) to assess future water supply scenarios under varying climate conditions. Findings revealed that the watershed is highly vulnerable to climate change, particularly under high-emission scenarios (SSP370 and SSP585), which are projected to significantly reduce streamflow and water availability. In contrast, the low-emission scenario (SSP126) showed relatively stable hydrological conditions. The study also highlighted the influence of socioeconomic factors, such as population growth and land-use changes, on increasing water demand. To address these challenges, the authors recommended adaptive management strategies, including improving water-use efficiency, protecting natural ecosystems, investing in climate-resilient infrastructure, and encouraging community participation in water governance. The study emphasizes the importance of integrating hydrological modeling into water resource planning to strengthen water security and support the achievement of Sustainable Development Goal

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Sustainable Water Supply, Sanitation, and Local Water Governance

According to Velasco, Sicat, Castillo, and Maddawin (2020), access to safe water and sanitation is recognized as a fundamental human right and is essential for achieving sustainable development. The authors emphasized that the provision of water supply and sanitation services in the Philippines relies heavily on local government units because water service delivery is a devolved function. They explained that water is a complex economic good, functioning both as a common resource and as a natural monopoly. Consequently, effective regulation, strategic investment coordination, and inter-local government cooperation are necessary to ensure efficient, equitable, and sustainable water service delivery. The study further highlighted that achieving universal access to potable water requires sound water infrastructure development, appropriate water tariff policies, and coordinated governance mechanisms across jurisdictions (Velasco et al., 2020).

2.3 Related Literature

Logistics management literature explains that route optimization relies on advanced algorithmic modeling to determine the most efficient and cost-effective delivery paths (Toth & Vigo, 2021). In the realm of software engineering, Pressman (2019) emphasizes the necessity of structured development methodologies to guarantee system reliability, particularly when integrating real-time data analytics and cloud-based tracking APIs. Furthermore, research underscores the critical role of operational visibility and fuel consumption monitoring in minimizing overhead costs and preventing the underutilization of corporate assets (Goldsby et al., 2018).

2.4 Synthesis of the Reviewed Literature

The reviewed foreign and local literature and studies provide a comprehensive understanding of the concepts, technologies, operational practices, and management approaches related to water distribution systems, fleet management, logistics operations, monitoring systems, decision-support technologies, and enterprise information systems. Collectively, these studies establish the theoretical and practical foundation for the development of the proposed **Enterprise**

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency.

A major similarity observed across the reviewed studies is the emphasis on the importance of **centralized information management systems** in improving operational performance. Several foreign studies, including those conducted by Beeny (1983), Liu and Xu (2001), Zhang (2021), and Liu et al. (2010), consistently highlighted that organizations perform more efficiently when operational data, monitoring functions, and management activities are consolidated into a single platform. These studies demonstrated that centralized systems improve information accessibility, reduce redundancy, enhance communication, and support faster decision-making processes. Similarly, local studies such as those conducted by Malenab et al. (2016), Israel (2009), and Velasco et al. (2020) emphasized the importance of effective information management and coordination in addressing challenges associated with water service delivery and resource management.

Another significant similarity among the reviewed studies is the growing reliance on **digital technologies and automation**. Research conducted by Kashihara et al. (2011), Lu et al. (2004), Chae et al. (2014), Feng and Ye (2021), and Bera (2021) demonstrated that automated systems contribute significantly to operational efficiency by reducing manual intervention, minimizing human errors, and enabling real-time monitoring of activities. These studies showed that organizations increasingly utilize digital tools to automate operational processes, collect data accurately, and generate analytical reports that support management decisions. In the context of

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

water distribution and fleet operations, automation becomes particularly important because operational activities such as scheduling, trip recording, fuel monitoring, and reporting often involve large amounts of data that are difficult to manage manually.

The reviewed studies also reveal a common trend toward the implementation of **data-driven decision-making systems**. Foreign studies on business analytics, operational analytics, integrated decision support systems, and operational risk management consistently indicate that organizations are shifting from intuition-based management approaches toward evidence-based decision-making. Chae et al. (2014) found that accurate operational data and analytics improve organizational performance, while Araz et al. (2020) emphasized the importance of integrating monitoring systems with analytical tools to improve risk management and operational control. Similarly, Bera (2021) demonstrated how operational analytics can support forecasting, planning, and resource allocation. These findings suggest that modern organizations increasingly depend on data to optimize operations, predict future requirements, and improve efficiency.

A similar trend can be observed in studies related to **transportation and fleet management systems**. Research conducted by Griffis and Goldsby (2007), Kotsialos and Vassilakopoulou (2023), van Heeswijk et al. (2019), and studies involving route optimization algorithms demonstrated that digital fleet management technologies improve delivery coordination, route planning, scheduling efficiency, and resource utilization. The findings suggest that transportation operations become significantly more effective when supported by integrated monitoring and

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

decision-support systems. These studies further emphasize the importance of real-time visibility and operational coordination in logistics environments.

In relation to water management, the reviewed literature reveals a growing trend toward the adoption of **integrated water management approaches**. Mitchell (2006), Austria and Lacbay (2025), Inocencio and Barker (2018), and Rola et al. (2016) all emphasized the need for comprehensive management systems that support planning, monitoring, coordination, and sustainability. These studies suggest that water-related challenges cannot be effectively addressed through isolated interventions alone. Instead, successful water management requires integrated systems capable of supporting multiple operational functions simultaneously. This finding aligns closely with the objectives of the proposed study, which seeks to integrate water distribution operations with fleet management activities within a unified platform.

Despite the positive developments reported in the reviewed studies, several recurring operational problems were identified. One of the most common issues is the continued dependence on **manual record-keeping and documentation processes**. Studies on workflow management, logistics operations, transportation systems, and operational monitoring consistently reported that manual recording methods often result in inaccurate data, delayed reporting, incomplete records, and increased administrative workload. In many organizations, information is still maintained through paper-based systems or disconnected spreadsheets, making it difficult to retrieve, verify, and analyze operational information. These limitations reduce organizational efficiency and hinder effective decision-making.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Another recurring problem identified in the literature is the difficulty of **monitoring fuel consumption and operational costs**. Studies involving fuel management systems, transportation management systems, and cost monitoring systems emphasized that organizations often struggle to accurately track fuel usage, maintenance expenses, and other operational costs. Without proper monitoring mechanisms, managers may find it difficult to identify inefficiencies, detect anomalies, or implement cost-reduction strategies. This issue is particularly relevant to fleet operations, where fuel expenses represent a significant portion of overall operational costs.

The reviewed studies also highlighted challenges associated with **operational visibility and coordination**. Several researchers noted that organizations often experience communication gaps between operational personnel and management teams due to fragmented information systems. This problem leads to delayed responses, inefficient scheduling, duplication of work, and poor coordination among stakeholders. Local studies on water governance and service delivery similarly reported difficulties in monitoring operational activities and coordinating resources across multiple organizational levels.

Furthermore, the literature identified problems related to **data quality and reliability**. Heino et al. (2019) found that operational systems may suffer from inconsistencies in data recording and documentation practices. Similarly, studies involving computerized monitoring systems and operational analytics stressed that inaccurate or incomplete data can negatively affect decision-making processes. Since management decisions depend heavily on the quality of

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

available information, ensuring accurate data collection remains a critical challenge in many operational environments.

Although numerous studies have investigated fleet management systems, transportation management systems, operational analytics, monitoring technologies, and water management solutions, several important research gaps remain. One notable gap is that most existing studies focus on only one specific operational area. Some studies focus exclusively on route optimization, while others concentrate on fuel monitoring, water governance, leak detection, transportation scheduling, analytics, or decision-support systems. Very few studies attempt to integrate these functionalities into a single enterprise-level platform.

Another research gap identified in the literature is the limited integration between **water distribution management and fleet management operations**. Existing studies generally treat these operational areas as separate systems. Water management studies primarily focus on resource planning, governance, sustainability, and infrastructure, whereas fleet management studies focus on transportation, routing, scheduling, and logistics. As a result, there remains limited research on systems capable of managing both operational domains simultaneously.

A further gap exists in the area of **centralized operational reporting and monitoring for water distribution enterprises**. While many studies discuss monitoring technologies and analytics, relatively few provide practical solutions that combine delivery monitoring, trip recording, fuel tracking, scheduling management, reporting, and decision-support functionalities within a single platform specifically designed for water distribution organizations. This limitation creates

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

opportunities for the development of integrated enterprise systems capable of addressing multiple operational challenges simultaneously.

The reviewed local studies also reveal a shortage of technology-based solutions specifically designed for Philippine water distribution enterprises. Most local studies focus on water governance, water resource management, infrastructure development, water quality, climate resilience, and sustainability. Although these studies provide valuable insights regarding water-related challenges, they offer limited discussion on enterprise-level digital management platforms that can support daily operational activities. Consequently, there remains a need for localized systems that address the operational requirements of water distribution businesses in the Philippine setting.

The proposed study seeks to address these identified gaps through the development of a **Centralized Fleet Management and Water Distribution System**. Unlike previous studies that focus on individual operational components, the proposed system integrates multiple functionalities into a single platform. Specifically, the system combines delivery scheduling, trip recording, fuel consumption monitoring, operational reporting, fleet tracking, and centralized information management. By integrating these functions, the proposed platform aims to improve operational visibility, enhance coordination, reduce administrative workload, and increase overall organizational efficiency.

Furthermore, the proposed study incorporates concepts from enterprise information systems, logistics management, transportation management, operational analytics, and water distribution

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

management. Through the integration of these concepts, the system provides a comprehensive solution capable of supporting both strategic and operational decision-making. The platform also addresses the limitations of manual processes by automating data collection, report generation, and operational monitoring activities.

Overall, the reviewed literature and studies strongly support the development of the proposed system. The findings consistently demonstrate the value of centralized management platforms, automated monitoring technologies, operational analytics, and integrated decision-support systems in improving organizational performance. At the same time, the reviewed studies reveal significant gaps related to system integration, operational coordination, and enterprise-level management of water distribution and fleet operations. By addressing these gaps, the proposed Enterprise Water Distribution and Fleet Management Platform contributes to existing knowledge and provides a practical solution for improving efficiency, reducing costs, enhancing monitoring capabilities, and supporting data-driven decision-making within water distribution enterprises.

CHAPTER 3

METHODOLOGY

This chapter presents the methodology and development process employed in the creation of the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency. It outlines the research design, software development

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

methodology, system architecture, tools and technologies utilized, data gathering techniques, testing procedures, evaluation criteria, and supporting system diagrams used throughout the study.

The development of the proposed platform aims to address operational challenges encountered in water distribution and fleet management, particularly in the areas of delivery scheduling, trip recording, fuel consumption monitoring, transportation expense documentation, and operational reporting. To ensure that the system effectively meets user requirements and organizational needs, a structured and systematic development approach was adopted. This approach enables the researchers to analyze existing operational processes, identify system requirements, design appropriate solutions, and evaluate the functionality of the developed platform.

Furthermore, this chapter discusses the technical framework and technologies used in developing the system, including the frontend, backend, database, and development environment. It also describes the methods used to gather information from stakeholders and the procedures conducted to test and evaluate the system's performance, usability, and security.

The diagrams and models presented in this chapter provide a visual representation of the system's structure, data flow, and user interactions. These diagrams serve as guides in understanding how the proposed platform operates and how information is processed within the system. Through the application of appropriate development methodologies and evaluation techniques, the researchers aim to ensure that the proposed platform is capable of improving

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

operational efficiency, enhancing data accuracy, supporting informed decision-making, and promoting cost-effective management practices in water distribution and fleet operations.

3.1 Research Design

This study employs a Developmental Research Design, a research approach commonly used in information technology and software development studies that focus on the creation, improvement, and evaluation of technological solutions. The purpose of this research design is to systematically develop a software application that addresses identified problems and improves existing operational processes. Unlike other research designs that primarily seek to describe, compare, or explain phenomena, developmental research focuses on producing a functional product and evaluating its effectiveness in addressing specific organizational needs.

The use of a developmental research design is appropriate for this study because the primary objective is to design, develop, and evaluate an Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency. The proposed platform is intended to address operational challenges encountered in water distribution and fleet management, including manual data recording, difficulties in tracking fuel consumption, lack of structured trip documentation, delays in generating operational reports, and inefficiencies in monitoring delivery performance. By developing a centralized information management

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

platform, the study seeks to provide a technological solution that enhances operational efficiency, improves record accuracy, and supports data-driven decision-making.

The developmental research process begins with identifying existing operational problems and gathering information from stakeholders through interviews and consultations. The collected data serve as the basis for determining system requirements, defining functional specifications, and establishing the overall objectives of the proposed platform. Understanding user needs and organizational processes is essential to ensure that the developed system effectively addresses the challenges experienced by water distribution enterprises.

Following the requirements analysis phase, the researchers proceed with the design and development of the system. This includes creating the system architecture, designing the user interface, developing the database structure, and implementing the functionalities required to support fleet management and water distribution operations. The platform is designed to facilitate delivery scheduling, trip recording, fuel consumption monitoring, transportation expense documentation, and operational reporting through a centralized and accessible web-based environment.

An important aspect of developmental research is the evaluation of the developed product. After implementation, the proposed system undergoes various testing and evaluation procedures to determine whether it meets the specified requirements and objectives. The evaluation focuses on assessing the functionality, usability, and security of the platform. User feedback and testing

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

results provide valuable information regarding the effectiveness of the system and identify areas that may require improvement or refinement.

Furthermore, the developmental research design supports an iterative approach to system improvement. Although the study follows a structured software development methodology, feedback gathered during testing and evaluation can be used to enhance system features and optimize performance. This ensures that the final product aligns with the operational requirements of the organization and delivers meaningful benefits to its users.

Through the application of a developmental research design, this study aims to produce a functional, reliable, and efficient Enterprise Water Distribution and Fleet Management Platform that contributes to improved operational management, better resource utilization, enhanced reporting capabilities, and cost-efficient business practices. The resulting platform is expected to provide a practical solution for managing water distribution and fleet operations while supporting organizational goals related to efficiency, transparency, and informed decision-making.

3.2 System Development Methodology

The system development methodology serves as the foundation for the development of the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency. It provides a structured and systematic approach that guides the researchers throughout the entire development process, from requirements gathering to system implementation and evaluation. By following a defined methodology, the researchers can ensure that each phase of development is properly planned and executed, reducing the possibility of

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

errors and improving the overall quality of the system. The methodology also helps establish clear objectives, organize development activities, and ensure that the system requirements are accurately translated into functional features.

Furthermore, the system development methodology serves as a roadmap that enables the researchers to monitor progress and maintain consistency throughout the project. It helps ensure that the developed platform effectively addresses the operational needs of water distribution and fleet management by providing a framework for analysis, design, development, testing, and deployment. Through a systematic development process, the researchers can evaluate the functionality, usability, and reliability of the system before implementation. As a result, the methodology plays a vital role in ensuring that the proposed platform is capable of improving operational efficiency, enhancing data management, and supporting informed decision-making within the organization.

The Waterfall Model will be used, consisting of the following phases:

1. Requirements Analysis

In this phase, we gathered and analyzed the requirements needed for the development of the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency. We conducted interviews with the client and reviewed the existing operational processes to identify the challenges and inefficiencies encountered in water

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

distribution and fleet management activities. Information regarding delivery scheduling, trip recording, fuel consumption monitoring, transportation expense documentation, and operational reporting was collected to determine the specific needs of the organization.

In this phase, we also identified the functional and non-functional requirements of the system.

The functional requirements included user account management, delivery scheduling, trip recording, fuel consumption monitoring, transportation expense documentation, report generation, and operational analytics. Meanwhile, the non-functional requirements focused on system usability, security, reliability, and accessibility. The requirements gathered during this phase served as the foundation for the design and development of the proposed platform, ensuring that the system addresses the operational needs of the organization and supports efficient and cost-effective fleet and water distribution management.

2. System Design

In this phase, we translated the identified system requirements into a detailed design for the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency. The system design phase served as the blueprint for the development of the platform by defining the system architecture, database structure, user interface, and overall system workflow. The purpose of this phase was to ensure that all required functionalities were properly planned before the implementation stage.

In this phase, we designed the system architecture to establish how users, system components, and the database interact with one another. The architecture was designed to support a

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

centralized web-based platform that enables administrators and drivers to access and manage operational information through a secure and responsive interface. The system architecture illustrates the flow of data from user input to data processing and storage, ensuring efficient information management and accessibility.

We also designed the database structure to organize and manage operational data effectively. The database was designed to store user information, vehicle records, delivery schedules, trip records, fuel consumption data, transportation expenses, and generated reports. Proper database design was implemented to ensure data integrity, consistency, and efficient retrieval of information required for reporting and analytics.

Furthermore, we designed the graphical user interface (GUI) to provide a user-friendly and accessible environment for system users. The interface design focused on simplicity, usability, and efficient navigation to enable users to perform tasks such as recording trips, monitoring fuel usage, managing delivery schedules, viewing reports, and accessing operational analytics.

Wireframes, system layouts, and screen designs were developed to visualize the appearance and functionality of the system before implementation.

To further illustrate the structure and operation of the proposed platform, supporting diagrams such as the Data Flow Diagram (DFD), Use Case Diagram, Entity Relationship Diagram (ERD), and System Architecture Diagram were created. These diagrams provide a visual representation of the system processes, data movement, database relationships, and user interactions, serving as guides during the development and implementation of the system.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

3. Implementation

In this phase, we developed the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency based on the system requirements and designs established during the previous phases. The implementation phase involved translating the system design into a functional web-based application by integrating the frontend, backend, and database components. During this stage, the required features and functionalities were coded, configured, and integrated to ensure that the system operates according to the specified requirements.

In this phase, we utilized HTML, CSS, and JavaScript to develop the frontend components of the system. HTML was used to create the structure and content of the web pages, while CSS was applied to enhance the visual appearance and user interface of the platform. JavaScript was used to provide interactive functionalities and improve the overall user experience. These technologies enabled the development of responsive and user-friendly interfaces that allow users to efficiently perform operational tasks within the system.

For the backend development, we utilized Python Flask as the server-side framework responsible for handling business logic, processing user requests, managing system operations, and facilitating communication between the user interface and the database. Flask provided the necessary tools for implementing system functionalities such as user authentication, data processing, report generation, and operational record management.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Firebase was utilized as the database platform for storing and managing system data. It served as the centralized repository for user information, vehicle records, delivery schedules, trip records, fuel consumption data, transportation expenses, and operational reports. The integration of Firebase enabled efficient data storage, retrieval, and synchronization, ensuring that operational information remains accessible and up-to-date.

Throughout the implementation phase, individual system modules were developed and integrated to create a unified platform capable of supporting water distribution and fleet management operations. The completed system was then prepared for testing and evaluation to verify that all functionalities operated correctly and met the requirements identified during the analysis phase.

4. Testing

In this phase, we conducted various testing procedures to verify that the proposed Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency functions correctly and meets the specified system requirements. The testing phase was performed to identify errors, validate system functionalities, and ensure that the platform operates reliably before deployment. Through systematic testing, we evaluated whether the developed system was capable of supporting water distribution and fleet management operations effectively.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

The testing process focused on assessing the accuracy, reliability, and performance of the system's features, including delivery scheduling, trip recording, fuel consumption monitoring, transportation expense documentation, report generation, and user account management. Any issues identified during testing were documented and corrected to improve the overall quality of the system. The testing phase also ensured that the system provided accurate outputs and responded appropriately to user inputs.

Unit Testing

In this phase, we performed Unit Testing to evaluate the individual components and modules of the system. Each module was tested independently to verify that it performed its intended function correctly. Functionalities such as user authentication, data entry, record management, report generation, and database operations were tested separately to identify coding errors and system defects. Unit Testing helped ensure that each component operated as expected before being integrated into the complete system.

User Acceptance Testing (UAT)

User Acceptance Testing (UAT) was conducted to determine whether the system satisfied the requirements and expectations of the intended users. During this process, the client and selected users interacted with the system and evaluated its functionality, usability, and overall performance. Feedback was collected regarding the ease of use, effectiveness of system features, accuracy of generated reports, and overall user experience. The results of the User Acceptance

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Testing served as the basis for validating the system's readiness for deployment and confirming that it effectively addressed the operational needs of the organization.

Through Unit Testing and User Acceptance Testing, the researchers ensured that the proposed platform met quality standards and provided reliable support for water distribution and fleet management operations.

5. Deployment (Prototype)

3.3 System Architecture

The proposed Centralized Fleet Management and Water Distribution System adopts a web-based client-server architecture that enables administrators to manage customer orders, monitor delivery operations, assign drivers, and generate operational reports through a centralized platform. The architecture is composed of four primary layers: the User Layer, Presentation Layer, Application Layer, and Database Layer.

The User Layer consists of the system administrator who is responsible for managing water distribution operations. The administrator creates customer orders, verifies delivery information, monitors delivery progress, schedules deliveries, assigns drivers, and generates operational

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

reports. Through the centralized platform, the administrator can access and manage all operational records in real time.

The Presentation Layer serves as the graphical user interface of the system. This layer is developed using HTML, CSS, and JavaScript to provide an interactive and responsive environment for users. Through the web interface, administrators can input customer information, manage delivery schedules, monitor fleet activities, track delivery status, and access generated reports. The web-based architecture allows users to access the system using standard web browsers without requiring additional software installation.

The Application Layer is developed using Python Flask and serves as the processing component of the system. This layer handles order validation, water availability checking, driver availability verification, delivery planning, scheduling, route management, delivery tracking, and report generation. When customer orders are submitted, the system validates the entered information and determines whether the order can proceed. If the information is incomplete or invalid, the order is rejected. Otherwise, the system stores the order and proceeds with operational planning activities.

The Database Layer utilizes Firebase as the centralized cloud database. This layer stores customer records, delivery schedules, driver information, vehicle information, water inventory records, delivery status updates, trip histories, and generated reports. Firebase enables real-time synchronization of data between the application and the user interface, ensuring that administrators have access to accurate and updated information.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

The system workflow begins when the administrator places a customer order. The system validates the order details before saving the information to the database. After validation, the system checks water availability and driver availability. If resources are available, delivery planning and driver assignment are performed. The system then schedules and dispatches the water delivery. During delivery operations, the administrator can monitor the delivery status through the tracking module. Once the delivery is completed, the system updates the delivery records and automatically generates operational, cost, and performance reports. These reports assist management in evaluating operational efficiency and making informed business decisions.

The integration of these architectural components provides a centralized environment for managing water distribution and fleet operations. By automating scheduling, monitoring deliveries, tracking operational activities, and generating reports, the system improves logistical efficiency, enhances service reliability, and reduces operational costs.

3.4 Tools and Technologies Used

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

The development of the proposed Centralized Fleet Management and Water Distribution System utilizes a combination of modern web development technologies and cloud-based services to ensure efficiency, scalability, reliability, and ease of maintenance. The selected tools and technologies are carefully chosen to support real-time data processing, centralized information management, and smooth interaction between users and the system. The system follows a full-stack web application approach, consisting of frontend technologies for user interaction, backend framework for processing logic, a cloud-based database for data storage, and a professional development environment for implementation.

Frontend Technologies (HTML, CSS, and JavaScript)

The frontend of the system is developed using HTML, CSS, and JavaScript, which serve as the core technologies for building web-based user interfaces. These technologies are essential in ensuring that users can interact with the system efficiently, especially administrators and authorized personnel who manage fleet operations, delivery scheduling, fuel tracking, and reporting.

HTML (HyperText Markup Language) is responsible for structuring the content of the web application. It defines the layout and organization of different interface components such as forms for data entry, tables for displaying records, navigation menus for system modules, and buttons for user actions. HTML ensures that all elements of the system are properly arranged and

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

accessible within the browser environment. It serves as the foundation of the entire user interface and allows the system to present information in a clear and structured manner.

CSS (Cascading Style Sheets) is used to enhance the visual appearance and design of the system. It controls the styling of HTML elements, including layout positioning, typography, color schemes, spacing, and responsiveness across different screen sizes and devices. Through CSS, the system is designed to be visually organized and user-friendly, ensuring that users can easily navigate through different sections without confusion. A well-designed interface is important in reducing user errors and improving the efficiency of system usage, particularly in operational environments where quick access to information is required.

JavaScript is responsible for adding interactivity and dynamic functionality to the system. It enables the system to respond to user actions in real time without requiring full page reloads. For example, JavaScript is used for form validation to ensure that correct and complete data is entered before submission. It also supports dynamic updates of content, such as displaying updated trip records or fuel logs instantly after changes are made. Additionally, JavaScript enables asynchronous communication with the backend through API requests, allowing smooth data exchange between the frontend and server. This improves the overall responsiveness and performance of the system, making it more efficient and user-friendly.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Backend Technology (Python Flask)

The backend of the system is developed using Python Flask, a lightweight and flexible web framework that is widely used for building web applications and APIs. Flask plays a critical role in handling the server-side operations of the system, including processing user requests, executing business logic, managing routes, and communicating with the database.

Flask is responsible for receiving data from the frontend, processing it according to system rules, and sending appropriate responses back to the user interface. In the context of the proposed system, Flask handles essential functions such as managing trip records, processing fuel consumption data, generating reports, handling authentication processes, and controlling access to different system modules.

One of the key strengths of Flask is its ability to support RESTful API development. This allows the system to maintain a clear separation between the frontend and backend, improving modularity and scalability. Through these APIs, the frontend can send requests such as adding a new delivery schedule or retrieving fleet status, and the backend responds with the required data in a structured format. This architecture improves system efficiency and makes it easier to maintain and upgrade in the future.

Flask was chosen for this system due to its simplicity, flexibility, and compatibility with Python. Its lightweight structure allows developers to build applications quickly without unnecessary complexity, while still providing the capability to scale as system requirements grow.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Additionally, Flask supports integration with various Python libraries, which can be useful for future enhancements such as data analytics, predictive maintenance, or advanced reporting features.

The modular nature of Flask also allows the system to be organized into separate components such as authentication modules, fleet management modules, and reporting modules. This improves code organization, reduces redundancy, and makes the system easier to debug and maintain.

Database Technology (Firebase)

The system utilizes Firebase, a cloud-based Backend-as-a-Service (BaaS) platform developed by Google, as its primary database solution. Firebase is designed to provide real-time data storage, synchronization, and secure cloud management, making it highly suitable for systems that require continuous updates and multi-user access.

Firebase is used to store and manage all critical operational data within the system. This includes delivery records, fleet and vehicle information, driver profiles, fuel consumption logs, trip histories, and system-generated reports. By centralizing all data in a cloud-based environment, the system ensures that information is consistently available and up to date across all users and devices.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

One of the most significant features of Firebase is its real-time database capability. This allows any changes made in the system to be instantly reflected across all connected users. For example, when a new delivery schedule is added or a trip is marked as completed, the updated information is immediately visible to administrators and other authorized users. This real-time synchronization improves coordination, reduces delays in communication, and enhances overall operational efficiency.

Firebase also provides robust security features through authentication services and database security rules. These features ensure that only authorized users can access or modify system data, thereby protecting sensitive operational information. User authentication can be managed through email/password login or other secure authentication methods supported by Firebase.

In addition, Firebase eliminates the need for manual server configuration and maintenance because it operates entirely in the cloud. This reduces infrastructure costs and simplifies system deployment. Its scalability allows the system to handle increasing amounts of data and user activity without performance degradation, making it suitable for both small-scale and large-scale operations.

Development Tool (Visual Studio Code)

The development of the system is carried out using Visual Studio Code (VS Code), a lightweight yet powerful integrated development environment (IDE) developed by Microsoft. VS Code is

widely used in modern web development due to its flexibility, performance, and extensive support for multiple programming languages and frameworks.

VS Code provides several features that enhance the development process, including syntax highlighting, intelligent code completion, debugging tools, and an integrated terminal. These features help developers write, test, and debug code efficiently within a single environment, reducing the need for multiple external tools.

Another important advantage of VS Code is its support for extensions, which significantly improves productivity and workflow. Extensions such as Python support enable better development of Flask applications, while Live Server allows real-time preview of frontend changes during development. Git integration also enables version control, allowing developers to track changes in the codebase and collaborate effectively.

In this system, VS Code is used to manage both frontend and backend development. It allows seamless switching between HTML, CSS, JavaScript, and Python files, making it easier to coordinate full-stack development tasks. Its debugging capabilities also help identify and fix errors early in the development process, improving overall system stability and reliability.

3.5 Data Gathering Techniques

In developing the proposed Centralized Fleet Management and Water Distribution System, we utilized appropriate data gathering techniques to ensure that the system is based on accurate

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

requirements and aligned with the actual needs of the users. The methods used in this phase include **interview with the client** and **observation**, which helped us understand the existing workflow, identify operational problems, and determine the necessary system improvements.

Interview with the Client

We conducted an interview with the client to gather detailed information regarding the current fleet management and water distribution processes. This method allowed us to directly communicate with the client and obtain first-hand information about how their operations are being carried out, as well as the challenges they encounter in their daily activities.

During the interview, the client explained that their current system relies heavily on manual processes such as handwritten logs and basic spreadsheet encoding for recording delivery schedules, trip details, and fuel consumption. According to the client, this method often leads to delays in updating records and increases the risk of errors and data inconsistencies.

The client also stated that consolidating operational reports takes a significant amount of time because data is collected from multiple sources and processed manually. This affects the timeliness of decision-making, especially when immediate access to accurate information is required for monitoring fleet activities and deliveries.

Furthermore, the client emphasized the difficulty in tracking vehicle usage and monitoring delivery status in real time due to the absence of a centralized system. Communication between

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

administrators and drivers is also not fully streamlined, which sometimes results in delays or missing updates regarding trip progress and delivery completion.

In addition, the client highlighted the need for a centralized platform that can store all operational data in one system, improve data accessibility, and automate report generation. They also expressed the importance of having a user-friendly interface and secure access control to ensure that only authorized personnel can manage system information.

Observation

We also conducted observation to further understand the actual workflow of the existing fleet management and water distribution operations. This allowed us to directly observe how daily activities are performed in practice and how information is recorded and managed within the current setup.

Through observation, we saw that delivery scheduling, trip recording, and fuel tracking are manually handled using logbooks and spreadsheet files. We also observed that data encoding is done repeatedly across different records, which increases the workload of personnel and may lead to redundancy and inconsistencies in the information.

It was also observed that updating and consolidating reports requires significant time and effort since data must be gathered from different sources before being organized into a final report.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

This process delays the availability of important operational information that is needed for monitoring and decision-making.

Additionally, we observed that there is no centralized platform that allows real-time tracking of deliveries and fleet activities. As a result, communication between administrators and drivers is often dependent on manual updates, which may cause delays or miscommunication during operations.

The observation helped us identify key inefficiencies in the current system, particularly in terms of manual data handling, lack of real-time monitoring, and difficulty in maintaining accurate and organized records. These findings were essential in determining the features that should be included in the proposed system.

3.6 Testing Procedures

In the development of the proposed Centralized Fleet Management and Water Distribution System, we will implement structured testing procedures to ensure that the system will function properly, meet the required specifications, and satisfy the needs of the intended users. Testing is considered a critical phase in the system development process because it helps identify errors, validate system functionality, and ensure that the system performs efficiently under expected conditions. It also ensures that both individual components and the overall system design are aligned with the objectives of the study.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

The testing process will be carried out in two major phases, namely **Unit Testing** and **User Acceptance Testing (UAT)**. These testing methods are selected to evaluate the system at different levels of development—from individual modules to the perspective of the actual end user. Through these procedures, we aim to ensure that the system is not only functional but also reliable, accurate, and user-friendly.

Unit Testing

We will conduct unit testing during the development phase of the system to evaluate each individual module or component separately. The main purpose of this testing method is to ensure that every function of the system works correctly before it is integrated with other modules. By isolating each component, we can easily identify errors, fix issues early, and improve the overall quality of the system.

Each module of the system will be tested independently based on its specific function. These include modules such as user authentication, data entry forms, trip management, fuel monitoring, delivery scheduling, and report generation. For instance, we will test the login module to ensure that it correctly validates user credentials, restricts unauthorized access, and properly redirects users based on their roles. This is important to ensure that system security and access control are properly implemented.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

We will also test the data entry modules to ensure that all information inputted by the user is properly captured, validated, and stored in the database. This includes checking whether required fields are enforced, whether incorrect data formats are rejected, and whether submitted data is accurately saved in Firebase. In addition, we will verify that data retrieval functions work correctly by ensuring that stored records can be displayed properly on the user interface without missing or incorrect information.

Furthermore, we will test the functionality of the trip management module, which includes recording trip details, assigning deliveries, and updating trip status. We will ensure that all updates made in the system are correctly reflected in the database and displayed in real time on the interface. The fuel monitoring module will also be tested to ensure that fuel consumption records are accurately stored and can be retrieved for reporting purposes.

During unit testing, we will also focus on validation and error handling mechanisms. We will check whether the system properly handles incomplete inputs, incorrect formats, and invalid data entries. Error messages will also be tested to ensure that they are clear and helpful for users in correcting their input.

Whenever errors or issues are identified during unit testing, we will immediately correct them and retest the affected module. This process will be repeated until the module functions correctly and meets the expected output. This iterative approach ensures that each component is stable and reliable before it is combined with other system modules.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Overall, unit testing will allow us to ensure that each part of the system works correctly in isolation, reducing the risk of system failure during integration and improving the overall quality and stability of the system.

User Acceptance Testing (UAT)

After completing unit testing and system integration, we will conduct User Acceptance Testing (UAT) with the client to determine whether the system meets their requirements and expectations. This phase is essential because it evaluates the system from the perspective of the actual end user and ensures that it is suitable for real-world use.

During UAT, we will present the developed system to the client and allow them to perform actual operational tasks using the system. These tasks will include managing delivery schedules, recording trip information, monitoring fleet activities, tracking fuel consumption, and generating reports. We will observe how the client interacts with the system and how effectively they are able to complete these tasks using the provided interface.

We will also assess how intuitive and user-friendly the system is from the client's perspective. This includes evaluating whether the navigation is easy to understand, whether the system layout is organized, and whether users can quickly access the necessary functions without confusion or difficulty. The ease of use is an important factor because the system is intended to be used in daily operations where efficiency is essential.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

During this stage, we will gather feedback from the client regarding the system's functionality, usability, and overall performance. The client's feedback will help us determine whether the system successfully addresses the problems identified during the data gathering phase. We will also take note of any suggestions for improvement, particularly in terms of interface design, workflow optimization, and additional features that may enhance system performance.

In addition, we will evaluate whether the system improves operational efficiency compared to the current manual process. This includes assessing whether data entry is faster, reporting is more efficient, and whether information is easier to access and manage. We also expect to evaluate whether communication and coordination between users are improved through the centralized system.

Any issues or improvements identified during UAT will be documented and, if necessary, revised to further enhance the system. This ensures that the final version of the system will meet the client's expectations and be fully suitable for deployment.

UAT is considered a crucial step in the development process because it validates not only the technical functionality of the system but also its practicality and usefulness in actual operations.

3.7 Evaluation Criteria:

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Functionality refers to how well the system performs its intended tasks and whether all features operate correctly according to the system requirements. In the context of the proposed system, functionality is considered one of the most important evaluation criteria because the system is designed to manage critical operations such as fleet monitoring, water delivery scheduling, trip recording, fuel tracking, and report generation.

We will evaluate functionality by checking whether each module of the system works as expected under normal and operational conditions. This includes verifying that all input, process, and output functions are correctly implemented and that the system produces accurate and reliable results. For example, when a user encodes a delivery schedule, the system should properly store the data in the database and display it correctly in the interface without errors or missing information.

We will also evaluate whether the system supports real-time data processing, especially in terms of updating trip statuses, recording fuel consumption, and reflecting changes in fleet operations. Since the system is intended to improve operational efficiency, it is important that all updates made by users are immediately reflected across the system without delays or inconsistencies.

Another important aspect of functionality is data accuracy. We will assess whether the system correctly processes and retrieves stored data from the database. This includes ensuring that reports generated by the system contain complete and accurate information based on actual records. Any discrepancies between input data and system output will be considered a functional issue that needs to be addressed.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

In addition, we will evaluate the system's ability to handle multiple users and simultaneous operations. Since fleet management involves coordination between administrators and drivers, the system should be able to support concurrent access without data loss or system errors.

We will also test the system's error handling capability. This involves checking whether the system can properly manage invalid inputs, incomplete forms, or unexpected user actions. The system should display appropriate error messages and prevent incorrect data from being saved into the database.

Overall, functionality ensures that the system performs all required tasks effectively and reliably, making it a critical factor in determining whether the system is ready for deployment.

Usability

Usability refers to how easy and efficient the system is for users to operate. It focuses on the user experience, interface design, and overall accessibility of the system. In this study, usability is an important criterion because the system will be used by administrators and personnel who may have varying levels of technical knowledge.

We will evaluate usability by examining how users interact with the system interface, including navigation, layout design, and ease of understanding system functions. The system is expected to

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

provide a clear and organized interface that allows users to perform tasks such as encoding data, viewing records, and generating reports without confusion.

One of the main aspects of usability is simplicity. We will assess whether the system is easy to understand and whether users can quickly learn how to operate it without requiring extensive training. A well-designed system should minimize complexity and allow users to accomplish tasks efficiently.

We will also evaluate the consistency of the system interface. This includes checking whether buttons, forms, and menus are arranged in a logical and uniform manner throughout the system. Consistency is important because it reduces user errors and improves navigation efficiency.

Another important factor is efficiency of use. We will assess whether users can complete tasks in a reasonable amount of time compared to the previous manual process. For example, tasks such as generating reports or searching for records should be faster and more convenient in the proposed system.

We will also consider accessibility in terms of system responsiveness and compatibility with different devices. The system should be usable on various screen sizes and should provide a smooth experience without lag or difficulty in interaction.

User feedback will also be an important part of evaluating usability. We will gather comments from the client regarding their experience using the system, including any difficulties encountered, suggestions for improvement, and overall satisfaction with the interface design.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

In summary, usability ensures that the system is not only functional but also user-friendly, efficient, and practical for daily operations.

Security

Security refers to the protection of system data, user access, and overall system integrity. In a centralized fleet management and water distribution system, security is a critical requirement because the system handles important operational data such as delivery schedules, vehicle information, fuel records, and user credentials.

We will evaluate security by assessing how well the system protects sensitive data from unauthorized access and potential misuse. One of the primary security features to be evaluated is user authentication. The system should ensure that only registered and authorized users are allowed to access specific system modules. Login credentials must be properly validated before granting access to the system.

We will also evaluate role-based access control, which ensures that users have different levels of access depending on their role. For example, administrators should have full access to manage records and generate reports, while drivers or other personnel may only have limited access to update trip-related information. This helps prevent unauthorized modification or deletion of important data.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

Another important aspect of security is data protection. We will assess whether all stored data in the database is properly secured using Firebase security rules. This includes ensuring that data cannot be accessed, modified, or deleted by unauthorized users. Proper encryption and secure data transmission methods will also be considered in evaluating system security.

We will also evaluate system protection against invalid or malicious inputs. The system should be able to detect and prevent attempts such as incorrect data injection, unauthorized data manipulation, or accidental corruption of records. Input validation mechanisms should be properly implemented to maintain data integrity.

In addition, we will assess the system's ability to maintain data backup and recovery. Since operational data is critical, the system should be capable of recovering information in case of unexpected errors or system failures.

Overall, security ensures that the system is reliable, protected, and safe to use, especially when handling sensitive operational and administrative data.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

SUPPORTING DIAGRAMS (Included within Chapter 3)

Data Flow Diagram (DFD – Level 0)

Figure X. DFD Level 0 (Context Diagram)

Figure X illustrates the DFD Level 0 or Context Diagram of the proposed **Enterprise Water Distribution and Fleet Management Platform**. The diagram presents the overall interaction between the system and its external entities, namely the **Administrator** and the **Driver**. It provides a high-level representation of how information flows into and out of the system.

The **Administrator** is the primary user responsible for managing the operations of the water distribution business. The administrator enters customer order details, manages driver information, prepares delivery schedules, and monitors water inventory through the system.

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

These data serve as the primary inputs required for the operation and management of water delivery services.

After processing the information, the system generates reports and analytics that provide insights into delivery performance, fuel consumption, and overall operational efficiency. The system also provides delivery status updates and notifications to inform the administrator about important operational events, such as delayed deliveries, unavailable drivers, or scheduling conflicts. These outputs enable administrators to monitor operations effectively and make informed decisions regarding resource allocation and service delivery.

The system also interacts with the **Driver**, who serves as the personnel responsible for carrying out delivery operations. The system provides the driver with delivery assignments, delivery schedules, and route information necessary to complete assigned tasks. This information helps ensure that deliveries are conducted according to the planned schedule and designated routes.

In return, the driver submits delivery status updates, fuel consumption records, and odometer readings to the system. These data allow the system to track delivery progress, monitor fuel usage, evaluate vehicle performance, and maintain accurate operational records. The information collected from drivers contributes to the generation of reports and analytics that support management decision-making.

Overall, the DFD Level 0 demonstrates how the proposed Enterprise Water Distribution and Fleet Management Platform serves as a centralized system that facilitates communication between administrators and drivers. By integrating order management, delivery scheduling, fleet

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

monitoring, fuel tracking, and reporting functions, the system improves operational efficiency, enhances data accuracy, and supports effective management of water distribution activities.

3.11 Use Case Diagram

Use Case Diagram Explanation

The Use Case Diagram of the proposed **Enterprise Water Distribution and Fleet Management Platform for Optimized Operations and Cost Efficiency** illustrates the functional interactions between the system and its primary users. It serves as a graphical representation of the system's operational requirements by identifying the actors involved and the services that the system provides to support water distribution and fleet management activities. Through this model, the relationships between users and system functionalities become more

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

evident, allowing stakeholders to understand how information is processed, managed, and utilized throughout daily operations.

The proposed platform is designed to address the challenges commonly encountered in water distribution businesses, including inefficient scheduling procedures, fragmented record management, limited operational visibility, inconsistent monitoring of fuel consumption, and delays in generating management reports. By integrating essential operational functions into a centralized platform, the system facilitates coordinated communication among personnel, promotes accurate data management, and supports informed decision-making through real-time access to operational information.

The Use Case Diagram identifies two primary actors within the system: the **Administrator** and the **Driver**. Each actor performs specific responsibilities that contribute to the overall workflow of the organization. While the administrator focuses on planning, coordination, monitoring, and management activities, the driver is responsible for executing delivery operations and providing operational feedback to the system. The interaction between these actors creates a continuous exchange of information that supports the effective management of water distribution services.

Administrator

The Administrator serves as the primary decision-maker and operational manager within the proposed platform. This actor possesses the highest level of system access and is responsible for supervising various business processes that directly influence service delivery, resource

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

utilization, and operational efficiency. Through the system, the administrator gains access to integrated tools that facilitate planning, monitoring, reporting, and resource management.

One of the fundamental functions available to the administrator is system authentication through the **Login** process. Authentication establishes a secure access mechanism that protects sensitive organizational information from unauthorized use. Since the platform stores operational records, customer information, inventory data, and delivery transactions, implementing secure login procedures is essential for maintaining data integrity and protecting organizational assets. Authentication also enables accountability by ensuring that system activities can be traced to authorized users.

After gaining access to the platform, the administrator can perform **Customer Order Management**, which serves as the foundation of the delivery process. Customer orders represent the primary source of operational demand and contain critical information required for service fulfillment. Through this functionality, administrators can record customer requests, update transaction details, verify delivery information, and maintain organized customer records. The digital management of customer orders reduces dependence on manual documentation while improving accessibility and record accuracy. Furthermore, centralized order management enables faster retrieval of historical transactions, allowing the organization to monitor customer demand patterns and improve service responsiveness.

Another important administrative responsibility involves **Driver Management**. Effective coordination of drivers is essential to ensuring timely and reliable delivery operations. Through

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

this function, administrators can maintain driver profiles, monitor personnel availability, assign responsibilities, and manage workforce records. Maintaining accurate driver information contributes to efficient personnel allocation and minimizes scheduling conflicts. Additionally, the availability of centralized driver records supports performance evaluation and workforce planning by providing management with relevant operational information.

The administrator is also responsible for **Water Inventory Management**, which involves monitoring the availability and movement of water supplies required to meet customer demand. Inventory control plays a significant role in maintaining operational continuity because inadequate stock levels can disrupt service delivery and negatively affect customer satisfaction. Through the proposed platform, inventory information is continuously monitored and updated, allowing administrators to identify shortages before they impact operations. The availability of real-time inventory records also supports procurement planning and resource allocation decisions, ensuring that sufficient supplies are available to support scheduled deliveries.

The **Schedule Deliveries** function represents a critical component of the proposed platform because it directly influences service efficiency and customer satisfaction. Delivery scheduling involves organizing customer orders into manageable delivery plans based on operational constraints such as vehicle availability, driver availability, delivery priorities, and geographic considerations. In traditional operations, scheduling activities are often performed manually, making them susceptible to errors, conflicts, and inefficiencies. The proposed system streamlines this process by centralizing scheduling information and providing administrators with a

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

structured environment for coordinating delivery activities. Through effective scheduling, organizations can improve resource utilization, reduce delays, and enhance service reliability.

Closely related to scheduling is the **Assign Deliveries** functionality. Once deliveries have been organized, administrators must allocate tasks to appropriate drivers. This process involves matching delivery requirements with available personnel and resources. Proper assignment contributes to balanced workload distribution, minimizes operational bottlenecks, and promotes accountability within the organization. By recording delivery assignments digitally, the system establishes a transparent record of responsibilities, making it easier to monitor task completion and evaluate operational performance.

In addition to planning activities, administrators must continuously evaluate ongoing operations. This responsibility is supported through the **Monitor Fleet Operations** function. Fleet monitoring provides visibility into delivery activities, vehicle utilization, and operational progress. Access to operational information allows administrators to identify delays, inefficiencies, and emerging issues that may affect service performance. By maintaining awareness of fleet activities, management can respond more effectively to operational disruptions and implement corrective measures when necessary. Enhanced visibility also contributes to improved coordination between administrative personnel and drivers.

Another significant management function is **Monitor Fuel Consumption**. Fuel expenditures represent a major operational cost for distribution businesses, making fuel management an important aspect of cost-control initiatives. Through the proposed platform, administrators can

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

review fuel consumption records submitted by drivers and evaluate fuel utilization patterns across the fleet. The availability of fuel-related information supports performance analysis and enables the identification of unusual consumption trends that may indicate inefficiencies or operational concerns. By continuously monitoring fuel usage, organizations can develop strategies aimed at reducing costs and improving overall fleet efficiency.

The platform further supports management activities through **Generate Reports and Analytics**.

One of the limitations of traditional record-keeping methods is the amount of time required to consolidate information from multiple sources. The proposed system addresses this challenge by automatically compiling operational data into meaningful reports and analytical summaries.

These reports provide valuable insights into delivery performance, resource utilization, fuel expenditures, inventory status, and workforce productivity. The availability of timely and accurate reports strengthens managerial decision-making by transforming operational data into actionable information. Through analytical reporting, management can evaluate organizational performance, identify opportunities for improvement, and support long-term strategic planning.

The administrator also benefits from the **Receive Notifications** function, which provides immediate awareness of important operational events. Notifications serve as an early warning mechanism by alerting administrators about situations that require attention, such as delivery delays, inventory shortages, unavailable drivers, or unusual fuel consumption patterns. Timely notifications enable management to respond proactively to emerging issues before they escalate

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

into larger operational problems. As a result, the organization becomes more capable of maintaining service continuity and operational stability.

Driver

The Driver functions as the operational actor responsible for executing delivery activities and providing field-generated information to the system. Although drivers possess fewer system privileges than administrators, their participation is essential because they serve as the primary source of real-time operational data.

Similar to administrators, drivers begin system interaction through the **Login** function.

Authentication ensures that delivery information is accessed only by authorized personnel and prevents unauthorized modifications to operational records. Secure access also contributes to accountability by associating operational activities with specific users.

One of the most important functions available to drivers is **View Delivery Assignments**. This feature allows drivers to access information regarding the deliveries assigned to them by administrators. By providing clear and organized assignment details, the system reduces communication errors and ensures that drivers understand their responsibilities. Access to assignment information improves operational coordination and supports the timely execution of delivery activities.

Drivers may also access **View Delivery Schedule**, which provides information regarding planned delivery dates and times. Access to scheduling information allows drivers to prepare for

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

upcoming tasks and manage their workload effectively. This functionality contributes to improved time management and supports adherence to delivery commitments established by the organization.

To facilitate navigation and delivery execution, drivers are provided with **View Delivery Address** functionality. Accurate destination information is essential for successful service fulfillment because errors in delivery locations can lead to delays, increased operational costs, and reduced customer satisfaction. By providing direct access to delivery addresses, the system improves delivery accuracy and reduces the likelihood of operational disruptions.

During the delivery process, drivers utilize **Update Delivery Status** to communicate the progress of assigned tasks. Delivery status updates provide management with real-time information regarding completed deliveries, ongoing operations, delays, and unsuccessful delivery attempts. The continuous exchange of status information enhances operational visibility and enables administrators to monitor service performance more effectively.

The driver is also responsible for **Submit Fuel Consumption Data**, which contributes to fleet monitoring and cost management activities. Fuel consumption records provide valuable insights into vehicle efficiency and operational expenditures. By collecting fuel-related information directly from drivers, the system establishes a reliable source of operational data that can be used for performance evaluation and financial analysis.

In addition, drivers utilize **Submit Odometer Readings** to record vehicle mileage. Odometer information supports preventive maintenance planning, vehicle utilization monitoring, and

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

performance assessment. Accurate mileage records help organizations maintain vehicle reliability while reducing the risk of unexpected mechanical failures that may disrupt service delivery.

Machine Learning Components

The proposed platform incorporates machine learning capabilities to support advanced decision-making and operational optimization. These intelligent functions distinguish the system from conventional management platforms by enabling predictive and analytical capabilities that extend beyond basic record management.

The **Generate Cost Predictions** function utilizes historical operational data to estimate future expenditures. By analyzing patterns related to fuel usage, delivery frequency, resource utilization, and operational performance, the system can produce cost forecasts that assist management in budgeting and financial planning activities. Predictive insights enable organizations to anticipate future resource requirements and develop strategies that improve financial sustainability.

The platform also includes **Optimize Delivery Addresses**, a machine learning-based function that supports delivery planning and resource allocation. Through the analysis of delivery locations and operational data, the system can identify more efficient delivery arrangements that minimize unnecessary travel and improve resource utilization. Optimization contributes to reduced fuel consumption, lower transportation costs, and improved delivery performance. The

PHINMA UNIVERSITY OF ILOILO

College of Information Technology Education

integration of intelligent optimization mechanisms aligns with the primary objective of achieving operational efficiency and cost effectiveness.

Summary

Overall, the Use Case Diagram demonstrates how the proposed Enterprise Water Distribution and Fleet Management Platform integrates operational management, delivery coordination, resource monitoring, and intelligent decision-support capabilities within a single environment. The interaction between administrators and drivers facilitates the continuous flow of information necessary for effective service delivery, while the inclusion of machine learning functions enhances the organization's ability to optimize operations and anticipate future requirements. By centralizing critical business processes, the proposed platform contributes to improved operational control, greater data accuracy, enhanced resource management, and more informed managerial decision-making.

End of Proposal

Note to the instructors handling this subject

CHED BSIT ALIGNMENT STATEMENT

This capstone project complies with CHED BSIT standards by demonstrating competencies in application development, database management, systems analysis and design, and emerging technologies such as machine learning. The project follows outcomes-based education principles and integrates ethical considerations, user safety, and data privacy.
